AMBA SPECIFICATION LICENCE

THIS END USER LICENCE AGREEMENT ("LICENCE") IS A LEGAL AGREEMENT BETWEEN YOU (EITHER A SINGLE INDIVIDUAL, OR SINGLE LEGAL ENTITY) AND ARM LIMITED ("ARM") FOR THE USE OF ARM'S INTELLECTUAL PROPERTY (INCLUDING, WITHOUT LIMITATION, ANY COPYRIGHT) IN THE RELEVANT AMBA SPECIFICATION ACCOMPANYING THIS LICENCE. ARM LICENSES THE RELEVANT AMBA SPECIFICATION TO YOU ON CONDITION THAT YOU ACCEPT ALL OF THE TERMS IN THIS LICENCE. BY CLICKING "I AGREE" OR OTHERWISE USING OR COPYING THE RELEVANT AMBA SPECIFICATION YOU INDICATE THAT YOU AGREE TO BE BOUND BY ALL THE TERMS OF THIS LICENCE.

"LICENSEE" means You and your Subsidiaries.

"Subsidiary" means, if You are a single entity, any company the majority of whose voting shares is now or hereafter owned or controlled, directly or indirectly, by You. A company shall be a Subsidiary only for the period during which such control exists.

1. Subject to the provisions of Clauses 2, 3 and 4, Arm hereby grants to LICENSEE a perpetual, non-exclusive, non-transferable, royalty free, worldwide licence to:
 - (i) use and copy the relevant AMBA Specification for the purpose of developing and having developed products that comply with the relevant AMBA Specification;
 - (ii) manufacture and have manufactured products which either: (a) have been created by or for LICENSEE under the licence granted in Clause 1(i); or (b) incorporate a product(s) which has been created by a third party(s) under a licence granted by Arm in Clause 1(i) of such third party's AMBA Specification Licence; and
 - (iii) offer to sell, sell, supply or otherwise distribute products which have either been (a) created by or for LICENSEE under the licence granted in Clause 1(i); or (b) manufactured by or for LICENSEE under the licence granted in Clause 1(ii).
2. LICENSEE hereby agrees that the licence granted in Clause 1 is subject to the following restrictions:
 - (i) where a product created under Clause 1(i) is an integrated circuit which includes a CPU then either: (a) such CPU shall only be manufactured under licence from Arm; or (b) such CPU is neither substantially compliant with nor marketed as being compliant with the Arm instruction sets licensed by Arm from time to time;
 - (ii) the licences granted in Clause 1(iii) shall not extend to any portion or function of a product that is not itself compliant with part of the relevant AMBA Specification; and
 - (iii) no right is granted to LICENSEE to sublicense the rights granted to LICENSEE under this Agreement.
3. Except as specifically licensed in accordance with Clause 1, LICENSEE acquires no right, title or interest in any Arm technology or any intellectual property embodied therein. In no event shall the licences granted in accordance with Clause 1 be construed as granting LICENSEE, expressly or by implication, estoppel or otherwise, a licence to use any Arm technology except the relevant AMBA Specification.
4. THE RELEVANT AMBA SPECIFICATION IS PROVIDED "AS IS" WITH NO REPRESENTATION OR WARRANTIES EXPRESS, IMPLIED OR STATUTORY, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF SATISFACTORY QUALITY, MERCHANTABILITY, NON-INFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE, OR THAT ANY USE OR IMPLEMENTATION OF SUCH ARM TECHNOLOGY WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADE SECRETS OR OTHER INTELLECTUAL PROPERTY RIGHTS.
5. NOTWITHSTANDING ANYTHING TO THE CONTRARY CONTAINED IN THIS AGREEMENT, TO THE FULLEST EXTENT PERMITTED BY LAW, THE MAXIMUM LIABILITY OF ARM IN AGGREGATE FOR ALL CLAIMS MADE AGAINST ARM, IN CONTRACT, TORT OR OTHERWISE, IN CONNECTION WITH THE SUBJECT MATTER OF THIS AGREEMENT (INCLUDING WITHOUT LIMITATION (I) LICENSEE'S USE OF THE ARM TECHNOLOGY; AND (II) THE IMPLEMENTATION OF THE ARM TECHNOLOGY IN ANY PRODUCT CREATED BY LICENSEE UNDER THIS AGREEMENT) SHALL NOT EXCEED THE FEES PAID (IF ANY) BY LICENSEE TO ARM UNDER THIS AGREEMENT. THE EXISTENCE OF MORE THAN ONE CLAIM OR SUIT WILL NOT ENLARGE OR EXTEND THE LIMIT. LICENSEE RELEASES ARM FROM ALL OBLIGATIONS, LIABILITY, CLAIMS OR DEMANDS IN EXCESS OF THIS LIMITATION.
6. No licence, express, implied or otherwise, is granted to LICENSEE, under the provisions of Clause 1, to use the Arm tradename, or AMBA trademark in connection with the relevant AMBA Specification or any products based thereon. Nothing in Clause 1 shall be construed as authority for LICENSEE to make any representations on behalf of Arm in respect of the relevant AMBA Specification.
7. This Licence shall remain in force until terminated by you or by Arm. Without prejudice to any of its other rights if LICENSEE is in breach of any of the terms and conditions of this Licence then Arm may terminate this Licence immediately upon giving written notice to You. You may terminate this Licence at any time. Upon expiry or termination

of this Licence by You or by Arm LICENSEE shall stop using the relevant AMBA Specification and destroy all copies of the relevant AMBA Specification in your possession together with all documentation and related materials. Upon expiry or termination of this Licence, the provisions of clauses 6 and 7 shall survive.

8. The validity, construction and performance of this Agreement shall be governed by English Law.

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status

The information in this document is final, that is for a developed product.

AMBA 5 CHI Architecture Specification

Preface

About this specification	xii
Feedback	xvii

Chapter 1

Introduction

1.1	Architecture overview	1-20
1.2	Topology	1-23
1.3	Terminology	1-24
1.4	Transaction classification	1-27
1.5	Coherence overview	1-31
1.6	Component naming	1-33
1.7	Read data source	1-35

Chapter 2

Transactions

2.1	Channels overview	2-38
2.2	Channel fields	2-39
2.3	Transaction structure	2-46
2.4	Transaction identifier fields	2-93
2.5	Transaction identifier field flows	2-100
2.6	Ordering	2-121
2.7	Address, Control, and Data	2-133
2.8	Data transfer	2-142
2.9	Request Retry	2-154

Chapter 3

Network Layer

3.1	System Address Map, SAM	3-160
3.2	Node ID	3-161
3.3	Target ID determination	3-162
3.4	Network layer flow examples	3-165

Chapter 4	Coherence Protocol	
4.1	Cache line states	4-170
4.2	Request types	4-172
4.3	Snoop request types	4-201
4.4	Request transactions and corresponding Snoop requests	4-204
4.5	Response types	4-208
4.6	Silent cache state transitions	4-220
4.7	Cache state transitions at a Requester	4-221
4.8	Cache state transitions at a Snoopee	4-232
4.9	Returning Data with Snoop response	4-251
4.10	Do not transition to SD	4-252
4.11	Hazard conditions	4-253
Chapter 5	Interconnect Protocol Flows	
5.1	Read transaction flows	5-256
5.2	Dataless transaction flows	5-266
5.3	Write transaction flows	5-270
5.4	Atomic transaction flows	5-273
5.5	Stash transaction flows	5-280
5.6	Hazard handling examples	5-283
Chapter 6	Exclusive accesses	
6.1	Overview	6-292
6.2	Exclusive monitors	6-293
6.3	Exclusive transactions	6-296
Chapter 7	Cache Stashing	
7.1	Overview	7-304
7.2	Write with Stash hint	7-306
7.3	Independent Stash request	7-307
7.4	Stash target identifiers	7-309
7.5	Stash messages	7-310
Chapter 8	DVM Operations	
8.1	DVM transaction flow	8-314
8.2	DVM Operation types	8-323
8.3	DVM Operations	8-330
Chapter 9	Error Handling	
9.1	Error types	9-342
9.2	Error response fields	9-343
9.3	Errors and transaction structure	9-344
9.4	Error response use by transaction type	9-345
9.5	Poison	9-355
9.6	Data Check	9-356
9.7	Use of interface parity	9-357
9.8	Interoperability of Poison and DataCheck	9-360
9.9	Hardware and software error categories	9-361
Chapter 10	Quality of Service	
10.1	Overview	10-364
10.2	QoS priority value	10-365
10.3	Repeating a transaction with higher QoS value	10-366
Chapter 11	System Debug, Trace, and Monitoring	
11.1	Data Source indication	11-368
11.2	SLC replacement hint	11-371

	11.3	MPAM	11-373
	11.4	Completer Busy	11-375
	11.5	Trace Tag	11-376
Chapter 12		Memory Tagging	
	12.1	Introduction	12-380
	12.2	Message extensions	12-381
	12.3	Tag coherency	12-382
	12.4	Read transaction rules	12-383
	12.5	Write transactions	12-386
	12.6	Dataless transactions	12-388
	12.7	Atomic transactions	12-389
	12.8	Stash transactions	12-390
	12.9	Snoop requests	12-391
	12.10	Home to Subordinate transactions	12-393
	12.11	Error response	12-394
	12.12	Requests and permitted tag operations	12-396
	12.13	TagOp field use summary	12-398
Chapter 13		Link Layer	
	13.1	Introduction	13-402
	13.2	Link	13-403
	13.3	Flit	13-404
	13.4	Channel	13-405
	13.5	Port	13-407
	13.6	Node interface definitions	13-408
	13.7	Increasing inter-port bandwidth	13-410
	13.8	Channel interface signals	13-414
	13.9	Flit packet definitions	13-418
	13.10	Protocol flit fields	13-424
	13.11	Link flit	13-450
Chapter 14		Link Handshake	
	14.1	Clock, and initialization	14-452
	14.2	Link layer Credit	14-453
	14.3	Low power signaling	14-454
	14.4	Flit level clock gating	14-455
	14.5	Interface activation and deactivation	14-456
	14.6	Transmit and receive link Interaction	14-462
	14.7	Protocol layer activity indication	14-468
Chapter 15		System Coherency Interface	
	15.1	Overview	15-474
	15.2	Handshake	15-475
Chapter 16		Properties, Parameters, and Broadcast Signals	
	16.1	Interface properties and parameters	16-478
	16.2	Optional interface broadcast signals	16-482
	16.3	Atomic transaction support	16-486
Appendix A		Message Field Mappings	
	A.1	Request message field mappings	A-491
	A.2	Response message field mappings	A-496
	A.3	Data message field mappings	A-497
	A.4	Snoop Request message field mappings	A-498
Appendix B		Communicating Nodes	
	B.1	Request communicating nodes	B-500

B.2 Snoop communicating nodes B-502

B.3 Response communicating nodes B-503

B.4 Data communicating nodes B-504

Appendix C

Revisions

Glossary

Preface

This preface introduces the *AMBA 5 CHI Architecture Specification*. It contains the following sections:

- *About this specification* on page xii
- *Using this specification* on page xii
- *Conventions* on page xiv
- *Additional reading* on page xvi
- *Feedback* on page xvii

About this specification

This specification describes the AMBA 5 *Coherent Hub Interface* (CHI) architecture.

Intended audience

This specification is written for hardware and software engineers who want to become familiar with the CHI architecture and design systems and modules that are compatible with the CHI architecture.

Using this specification

This book is organized into the following chapters:

Chapter 1 *Introduction*

Read this for an introduction to the CHI architecture and the terminology used in this specification.

Chapter 2 *Transactions*

Read this for an overview of the communication channels between nodes, the associated packet fields, transaction structures, transaction ID flows, and the supported transaction ordering.

Chapter 3 *Network Layer*

Read this for a description of the Network layer that is responsible for determining the node ID of a destination node.

Chapter 4 *Coherence Protocol*

Read this for an introduction to the coherence protocol.

Chapter 5 *Interconnect Protocol Flows*

Read this for examples of protocol flows for different transaction types.

Chapter 6 *Exclusive accesses*

Read this for a description of the mechanisms that the architecture includes to support Exclusive accesses.

Chapter 7 *Cache Stashing*

Read this for a description of the cache stashing mechanism whereby data can be installed in a cache.

Chapter 8 *DVM Operations*

Read this for a description of DVM operations that the protocol uses to manage virtual memory.

Chapter 9 *Error Handling*

Read this for a description of the error response requirements.

Chapter 10 *Quality of Service*

Read this for a description of the mechanisms that the protocol includes to support *Quality of Service* (QoS).

Chapter 11 *System Debug, Trace, and Monitoring*

Read this for a description of the mechanisms that provide additional support for the debugging, tracing, and performance measurement of systems.

Chapter 12 *Memory Tagging*

Read this for a description of the *Memory Tagging Extension* (MTE) that provides a mechanism to check the correct usage of data held in memory.

Chapter 13 *Link Layer*

Read this for a description of the Link layer that provides a mechanism for packet based communication between protocol nodes and the interconnect.

Chapter 14 *Link Handshake*

Read this for a description of the Link layer handshake requirements.

Chapter 15 *System Coherency Interface*

Read this for a description of the interface signals that support connecting and disconnecting components from both the Coherency and DVM domains.

Chapter 16 *Properties, Parameters, and Broadcast Signals*

Read this for a description of the optional signals that provide flexibility in configuring optional interface properties.

Appendix A *Message Field Mappings*

Read this for the field mappings for messages.

Appendix B *Communicating Nodes*

Read this for the node pairs that can legally communicate within the protocol.

Appendix C *Revisions*

Read this for a description of the technical changes between released issues of this specification.

Glossary

Read this for definitions of terms used in this specification.

Conventions

The following sections describe conventions that this specification can use:

- [Typographical conventions](#)
- [Timing diagrams](#)
- [Signals](#) on page xvi
- [Numbers](#) on page xvi

Typographical conventions

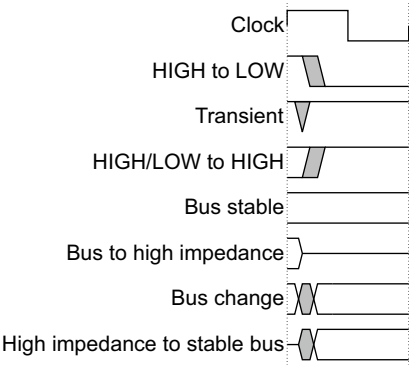

The typographical conventions are:

<i>italic</i>	Highlights important notes, introduces special terminology, and denotes internal cross-references and citations.
bold	Denotes signal names, and is used for terms in descriptive lists, where appropriate.
monospace	Used for assembler syntax descriptions, pseudocode, and source code examples. Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.
SMALL CAPITALS	Used for a few terms that have specific technical meanings.

Timing diagrams

The components used in timing diagrams are explained in the figure, [Key to timing diagram conventions](#). Variations have clear labels, when they occur. Do not assume any timing information that is not explicit in the diagrams.

Shaded bus and signal areas are undefined, so the bus or signal can assume any value within the shaded area at that time. The actual level is unimportant and does not affect normal operation.

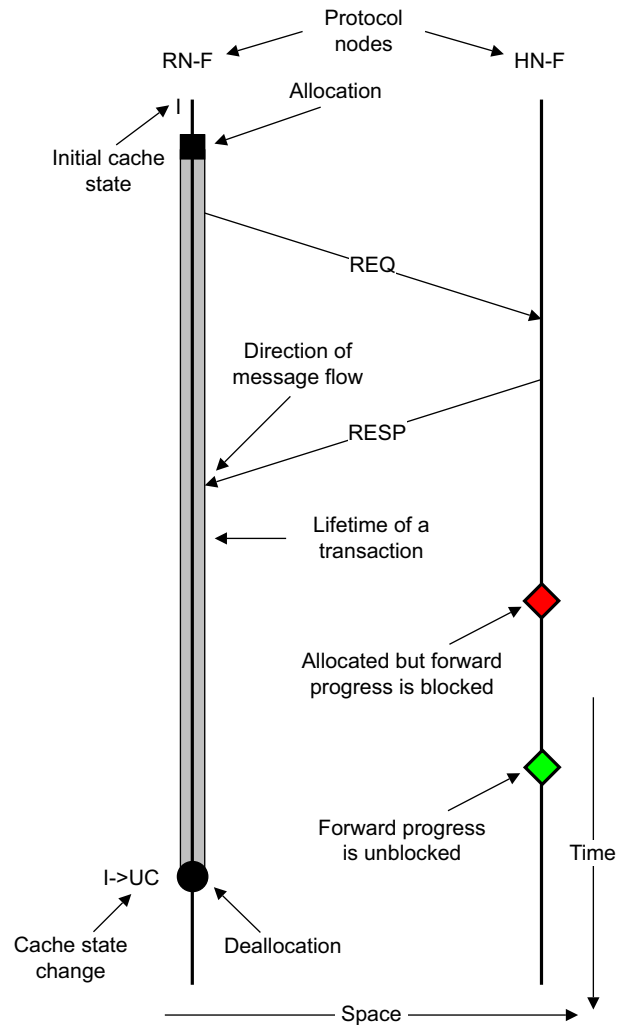

Key to timing diagram conventions

Timing diagrams sometimes show single-bit signals as HIGH and LOW at the same time and they look similar to the bus change that the [Key to timing diagram conventions](#) figure shows. If a timing diagram shows a single-bit signal in this way then its value does not affect the accompanying description.

Time-Space diagrams

The [Key to Time-Space diagram conventions](#) figure explains the format used to illustrate protocol flow.

Key to Time-Space diagram conventions

In the Time-Space diagram:

- The protocol nodes are positioned along the horizontal axis and time is indicated vertically, top to bottom.
- The lifetime of a transaction at a protocol node is shown by an elongated shaded rectangle along the time axis from allocation to the deallocation time.
- The initial cache state at the node is shown at the top.
- The diamond shape on the timeline indicates arrival of a request and whether its processing is blocked waiting for another event to complete.
- The cache state transition, upon the occurrence of an event, is indicated by I->UC.

Signals

The signal conventions are:

- Signal level** The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:
- HIGH for active-HIGH signals.
 - LOW for active-LOW signals.
- Lowercase n** At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. Both are written in a monospace font.

Additional reading

This section lists relevant publications from Arm.

See *Arm Developer* <https://developer.arm.com/documentation>, for access to Arm documentation.

Arm publications

- *AMBA® AXI and ACE Protocol Specification* (ARM IHI 0022).

Feedback

Arm welcomes feedback on its documentation.

Feedback on this specification

If you have comments on the content of this specification, send an e-mail to errata@arm.com. Give:

- The title, *AMBA 5 CHI Architecture Specification*.
- The number, ARM IHI 0050E.c.
- The page numbers to which your comments apply.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

Progressive terminology commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive.

Arm strives to lead the industry and create change.

Previous issues of this document included terms that can be offensive. We have replaced these terms. If you find offensive terms in this document, please contact terms@arm.com.

Chapter 1

Introduction

This chapter introduces the CHI architecture and the terminology used throughout this specification. It contains the following sections:

- *Architecture overview* on page 1-20
- *Topology* on page 1-23
- *Terminology* on page 1-24
- *Transaction classification* on page 1-27
- *Coherence overview* on page 1-31
- *Component naming* on page 1-33
- *Read data source* on page 1-35

1.1 Architecture overview

The CHI architecture is a scalable, coherent hub interface and on-chip interconnect used by multiple components. The CHI architecture allows for flexible topologies of component connections, driven by performance, power, and area system requirements.

1.1.1 Components

The components of CHI-based systems can comprise of:

- Standalone processors
- Processor clusters
- Graphic processors
- Memory controllers
- I/O bridges
- PCIe subsystems
- Interconnects

1.1.2 Key features

The key features of the architecture are:

- Scalable architecture, enabling modular designs that scale from small to large systems.
- Independent layered approach, comprising of Protocol, Network, and Link layer, with distinct functionalities.
- Packet-based communication.
- All transactions handled by an interconnect-based Home Node that co-ordinates required snoops, cache, and memory accesses.
- The CHI coherence protocol supports:
 - Coherency granule of 64-byte cache line.
 - Snoop filter and directory-based systems for snoop scaling.
 - Both MESI and MOESI cache models with forwarding of data from any cache state.
 - Additional partial and empty cache line states.
- The CHI transaction set includes:
 - Enriched transaction types that permit performance, area, and power efficient system cache implementation.
 - Support for atomic operations and synchronization within the interconnect.
 - Support for the efficient execution of Exclusive accesses.
 - Transactions for the efficient movement and placement of data, to move data in a timely manner closer to the point of anticipated use.
 - Virtual memory management through *Distributed Virtual Memory* (DVM) operations.
- Request retry to manage protocol resources.
- Support for end-to-end *Quality of Service* (QoS).
- Support for the Arm *Memory Tagging Extension* (MTE).
- Configurable data width to meet the requirements of the system.
- ARM TrustZone™ support on a transaction-by-transaction basis.
- Optimized transaction flow for coherent writes with a producer-consumer ordering model.
- Error reporting and propagation across components and interconnect for system reliability and integrity.

- Handling sub cache line data errors using Data Poisoning and per byte error indication.
- Power-aware signaling on the component interface:
 - Enabling flit-level clock gating.
 - Component activation and deactivation sequence for clock-gate and power-gate control.
 - Protocol activity indication for power and clock control.

1.1.3 Architecture layers

Functionality is grouped into the following layers:

- Protocol
- Network
- Link

Table 1-1 describes the primary function of each layer.

Table 1-1 Layers of the CHI architecture

Layer	Communication granularity	Primary function
Protocol	Transaction	The Protocol layer is the topmost layer in the CHI architecture. The function of the Protocol layer is to: <ul style="list-style-type: none">• Generate and process requests and responses at the protocol nodes.• Define the permitted cache state transitions at the protocol nodes that include caches.• Define the transaction flows for each request type.• Manage the protocol level flow control.
Network	Packet	The function of the Network layer is to: <ul style="list-style-type: none">• Packetize the protocol message.• Determine the source and target Node IDs required to route the packet over the interconnect to the required destination and add to the packet.
Link	Flit	The function of the Link layer is to: <ul style="list-style-type: none">• Provide flow control between network devices.• Manage link channels to provide deadlock-free switching across the network.

1.2 Topology

The CHI architecture is primarily topology-independent. However, certain topology-dependent optimizations are included in this specification to make implementation more efficient. Figure 1-1 shows three examples of topologies selected to show the range of interconnect bandwidth and scalability options that are available.

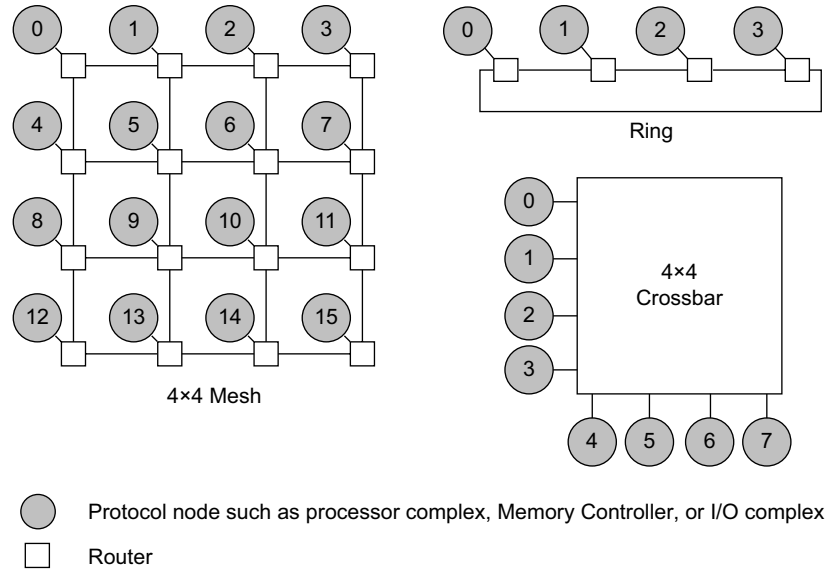

Figure 1-1 Example interconnect topologies

Crossbar	This topology is simple to build and naturally provides an ordered network with low latency. It is suitable where the wire counts are still relatively small. This topology is suitable for an interconnect with a small number of nodes.
Ring	This topology provides a trade-off between interconnect wiring efficiency and latency. The latency increases linearly with the number of nodes on the ring. This topology is suitable for a medium size interconnect.
Mesh	This topology provides greater bandwidth at the cost of more wires. It is very modular and can be easily scaled to larger systems by adding more rows and columns of switches. This topology is suitable for a larger scale interconnect.

1.3 Terminology

The following terms have a specific meaning in this specification:

Transaction

A transaction carries out a single operation. Typically, a transaction either reads from memory or writes to memory.

Message

A message is a protocol layer term that defines the granule-of-exchange between two components. Examples are:

- Request
- Data response
- Snooper request

A single Data response message might be made up of a number of packets.

Packet

A packet is the granule-of-transfer over the interconnect between endpoints. A message might be made up of one or more packets. For example, a single Data response message can be made up of 1 to 4 packets. Each packet contains routing information, such as destination ID and source ID that enables it to be routed independently over the interconnect.

Flit

Flow control unit (Flit) is the smallest flow control unit. A packet can be made up of one or more flits. All the flits of a given packet follow the same path through the interconnect.

———— **Note** ————

For CHI, all packets consist of a single flit.

Phit

Physical layer transfer unit (Phit) is defined as one transfer between two adjacent network devices. A flit can be made up of one or more phits.

———— **Note** ————

For CHI, all flits consist of a single phit.

PoS

Point of Serialization (PoS) is a point within the interconnect where the ordering between Requests from different agents is determined.

PoC

Point of Coherence (PoC) is a point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In a typical CHI-based system, it is the HN-F in the interconnect.

PoP

Point of Persistence (PoP) is the point in a memory system, if it exists, at or beyond the Point of Coherency, where a write to memory is maintained when system power is removed, and reliably recovered when power is restored to the affected locations in memory.

Downstream cache

A downstream cache is defined from the perspective of a Request Node. A downstream cache for a Request, is a cache that the Request accesses using CHI Request transactions. A Request Node can send a Request with data to allocate data into a downstream cache.

Requester

A component that starts a transaction by issuing a Request message. The term Requester can be used for a component that independently initiates transactions. The term Requester can also be used for an interconnect component that issues a downstream Request message independently or as a side-effect of other transactions that are occurring in the system.

Completer

Any component that responds to a transaction it receives from another component. A Completer can either be an interconnect component, such as Home Node or a Misc Node, or a component, such as a Subordinate, that is outside of the interconnect.

Subordinate

An agent that receives transactions and completes them appropriately. Typically, a Subordinate is the most downstream agent in a system. A Subordinate can also be referred to as a Completer or Endpoint.

Endpoint

Another name for a Subordinate component. As the name implies, an endpoint is the final destination for a transaction.

Protocol Credit

A credit, or guarantee, from a Completer that it will accept a transaction.

Link layer Credit

A credit, or guarantee, that a flit will be accepted on the other side of the link. A *Link layer Credit* (L-Credit) is a credit for a single hop at the Link layer.

ICN

Interconnect (ICN) is the CHI transport mechanism that is used for communication between protocol nodes. An ICN might include a fabric of switches connected in a ring, mesh, crossbar, or some other topology. The ICN might include protocol nodes such as Home Node and Misc Node. The topology of the ICN is IMPLEMENTATION DEFINED.

IPA

Intermediate Physical Address (IPA). In two stage address translation:

- Stage one results in an Intermediate Physical Address.
- Stage two provides the Physical Address.

RN

Request Node (RN) generates protocol transactions, including reads and writes, to the interconnect.

HN

Home Node (HN) is a node located within the interconnect that receives protocol transactions from Request Nodes, completes the required Coherency action, and returns a Response.

SN

Subordinate Node (SN) is a node that receives a Request from a Home Node, completes the required action, and returns a Response.

MN

Misc or Miscellaneous Node (MN) is a node located within the interconnect that receives DVM messages from Request Nodes, completes the required action, and returns a Response.

IO Coherent node

A Request Node that generates a subset of Snoopable requests in addition to Non-snoopable requests. The Snoopable requests that an IO Coherent node generates do not result in the caching of the received data in a coherent state. Therefore, an IO Coherent node does not receive any Snoop requests.

Snoopee

A Request Node that is receiving a snoop.

Write-Invalidate protocol

A protocol in which a Request Node writing to a cache line that is shared in the system must invalidate all the shared copies before proceeding with the write. The CHI protocol is a Write-Invalidate protocol.

In a timely manner

The protocol cannot define an absolute time within which something must occur. However, in a sufficiently idle system, it will make progress and complete without requiring any explicit action.

Inapplicable

A field value that indicates that the field is not used in the processing of the message.

1.4 Transaction classification

The protocol transactions that this specification supports, and their major classification, are listed in [Table 1-2](#).

Table 1-2 Transaction classification

Classification	Supporting transactions
Read	ReadNoSnp, ReadNoSnpSep
	ReadOnce
	ReadOnceCleanInvalid
	ReadOnceMakeInvalid
	ReadClean
	ReadNotSharedDirty
	ReadShared
	ReadUnique
	ReadPreferUnique
	MakeReadUnique
Dataless	CleanUnique
	MakeUnique
	Evict
	StashOnceUnique, StashOnceSepUnique
	StashOnceShared, StashOnceSepShared
	CleanShared
	CleanSharedPersist, CleanSharedPersistSep
	CleanInvalid
	MakeInvalid
Write	WriteNoSnpPtl, WriteNoSnpFull, WriteNoSnpZero
	WriteUniquePtl, WriteUniqueFull, WriteUniqueZero
	WriteUniquePtlStash, WriteUniqueFullStash
	WriteBackPtl, WriteBackFull
	WriteCleanFull
	WriteEvictFull, WriteEvictOrEvict

Table 1-2 Transaction classification (continued)

Classification	Supporting transactions
Combined Write	WriteNoSnpPtlCleanInv, WriteNoSnpPtlCleanSh, WriteNoSnpPtlCleanShPerSep
	WriteNoSnpFullCleanInv, WriteNoSnpFullCleanSh, WriteNoSnpFullCleanShPerSep
	WriteUniquePtlCleanSh, WriteUniquePtlCleanShPerSep
	WriteUniqueFullCleanSh, WriteUniqueFullCleanShPerSep
	WriteBackFullCleanInv, WriteBackFullCleanSh, WriteBackFullCleanShPerSep
	WriteCleanFullCleanSh, WriteCleanFullCleanShPerSep
Atomic	AtomicStore
	AtomicLoad
	AtomicSwap
	AtomicCompare
Other	DVMOp
	PrefetchTgt
	PCrdReturn

Table 1-2 Transaction classification (continued)

Classification	Supporting transactions
Snoop	SnpOnceFwd
	SnpOnce
	SnpStashUnique
	SnpStashShared
	SnpCleanFwd
	SnpClean
	SnpNotSharedDirtyFwd
	SnpNotSharedDirty
	SnpSharedFwd
	SnpShared
	SnpUniqueFwd
	SnpUnique
	SnpPreferUniqueFwd
	SnpPreferUnique
	SnpUniqueStash
	SnpCleanShared
	SnpCleanInvalid
	SnpMakeInvalid
	SnpMakeInvalidStash
	SnpQuery
	SnpDVMOp

Table 1-3 shows the representations of transactions.

Table 1-3 Representation of transactions

Specification use	Represents collectively
ReadOnce*	ReadOnce, ReadOnceCleanInvalid, and ReadOnceMakeInvalid
WriteNoSnp	WriteNoSnpPtl and WriteNoSnpFull
WriteUnique	WriteUniquePtl, WriteUniqueFull, WriteUniquePtlStash, and WriteUniqueFullStash
WriteBack	WriteBackPtl and WriteBackFull
StashOnce	StashOnceUnique and StashOnceShared
StashOnceSep	StashOnceSepUnique and StashOnceSepShared
StashOnce*	StashOnce and StashOnceSep

Table 1-3 Representation of transactions (continued)

Specification use	Represents collectively
StashOnce*Shared	StashOnceShared and StashOnceSepShared
StashOnce*Unique	StashOnceUnique and StashOnceSepUnique
CleanSharedPersist*	CleanSharedPersist and CleanSharedPersistSep
SnpStash*	SnpStashUnique and SnpStashShared
DBIDResp*	DBIDResp and DBIDRespOrd

1.5 Coherence overview

Hardware coherence enables system components to share memory without the requirement of software cache maintenance to maintain coherence.

Regions of memory are coherent if writes to the same memory location by two components are observable in the same order by all components.

1.5.1 Coherency model

Figure 1-2 shows an example coherent system that includes three Requester components, each with a local cache and coherent protocol node. The protocol permits cached copies of the same memory location to reside in the local cache of one or more Requester components.

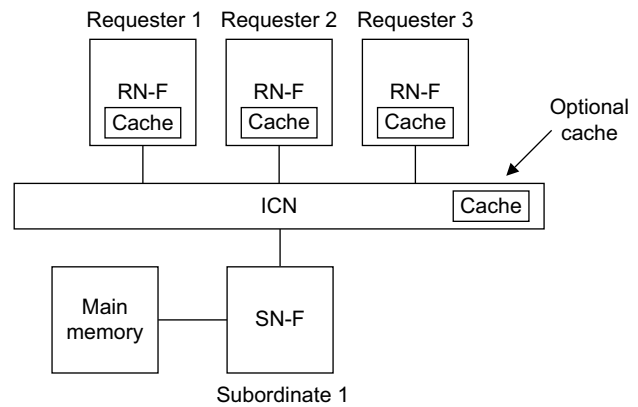

Figure 1-2 Example coherency model

The coherence protocol enforces that no more than one copy of a data value exists whenever a store occurs at an address location. The coherence protocol ensures all Requesters observe the correct data value at any given address location. After each store to a location, other Requesters can obtain a new copy of the data for their own local cache, to permit multiple cached copies to exist.

A cache line is defined as a 64-byte aligned memory region that is 64 bytes in size. All coherence is maintained at cache line granularity.

Main memory is only required to be updated before a copy of the memory location is no longer held in any cache. The protocol does not require main memory to be up to date at all times.

———— **Note** ————

Although not a requirement, it is acceptable to update main memory while cached copies still exist.

The protocol enables Requester components to determine whether a cache line is the only copy of a particular memory location or if there might be other copies of the same location. This ensures:

- If a cache line is the only copy, a Requester component can change the value of the cache line without notifying any other Requester components in the system.
- If a cache line might also be present in another cache, a Requester component must notify the other caches using an appropriate transaction.

1.5.2 Cache state model

To determine whether an action is required when a component accesses a cache line, the protocol defines cache states. Each cache state is based on the following cache line characteristics:

Valid, Invalid	When Valid, the cache line is present in the cache. When Invalid, the cache line is not present in the cache.
Unique, Shared	When Unique, the cache line exists only in this cache. When Shared, the cache line might exist in more than one cache, but this is not guaranteed.
Clean, Dirty	When Clean, the cache does not have responsibility for updating main memory. When Dirty, the cache line has been modified with respect to main memory, and this cache must ensure that main memory is eventually updated.
Full, Partial, Empty	A Full cache line has all bytes valid. A Partial cache line might have some bytes valid, where some include none or all bytes. An Empty cache line has no bytes valid.

Figure 1-3 shows the seven state cache model. [Cache line states on page 4-170](#) gives further information about each cache state.

A valid cache state name that is not Partial or Empty is considered to be Full. In Figure 1-3, UC, UD, SC, and SD are all Full cache line states.

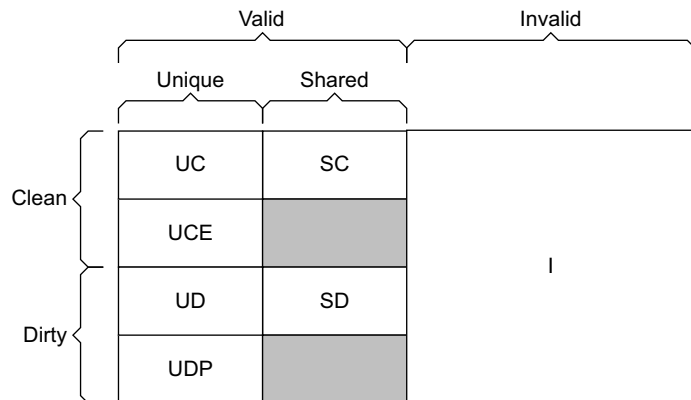

Figure 1-3 Cache state model

1.6 Component naming

Components are classified by CHI protocol node type:

RN	Request Node. Generates protocol transactions, including reads and writes, to the interconnect. A Request Node is further categorized as:
RN-F	Fully Coherent Request Node: <ul style="list-style-type: none"> Includes a hardware-coherent cache. Permitted to generate all transactions defined by the protocol. Supports all Snoop transactions.
RN-D	IO Coherent Request Node with DVM support: <ul style="list-style-type: none"> Does not include a hardware-coherent cache. Receives DVM transactions. Generates a subset of transactions defined by the protocol.
RN-I	IO Coherent Request Node: <ul style="list-style-type: none"> Does not include a hardware-coherent cache. Does not receive DVM transactions. Generates a subset of transactions defined by the protocol. Does not require snoop functionality.
HN	Home Node. Node located within the interconnect that receives protocol transactions from Request Nodes. A Home Node is further categorized as:
HN-F	Fully Coherent Home Node: <ul style="list-style-type: none"> Expected to receive all request types, except DVMOp. Includes a <i>Point of Coherence</i> (PoC) that manages coherency by snooping the required RN-Fs, consolidating the Snoop responses for a transaction, and sending a single response to the requesting Request Node. Expected to be the <i>Point of Serialization</i> (PoS) that manages order between memory requests. Might include a directory or snoop filter to reduce redundant snoops. <p>———— Note ———— IMPLEMENTATION SPECIFIC, can include an integrated ICN cache.</p>
HN-I	Non-coherent Home Node: <ul style="list-style-type: none"> Processes a limited subset of request types defined by the protocol. Does not include a PoC and is not capable of processing a Snooperable request. On receipt of a Snooperable request, it must respond with a protocol compliant message. Expected to be the PoS that manages order between IO requests targeting the IO subsystem.
MN	Miscellaneous Node. Receives a DVM transaction from a Request Node, completes the required action, and returns a response.

- SN** Subordinate Node. A Subordinate Node receives a request from a Home Node, completes the required action, and returns a response.
- A Subordinate Node is further categorized as:
- SN-F** A Subordinate Node type used for Normal memory. It can process Non-snoopable Read, Write, and Atomic requests, including exclusive variants of them, and *Cache Maintenance Operation* (CMO) requests.
 - SN-I** A Subordinate Node type used for peripherals or Normal memory. It can process Non-snoopable Read, Write, and Atomic requests, including exclusive variants of them, and CMO requests.

Figure 1-4 shows various protocol node types connected through an interconnect.

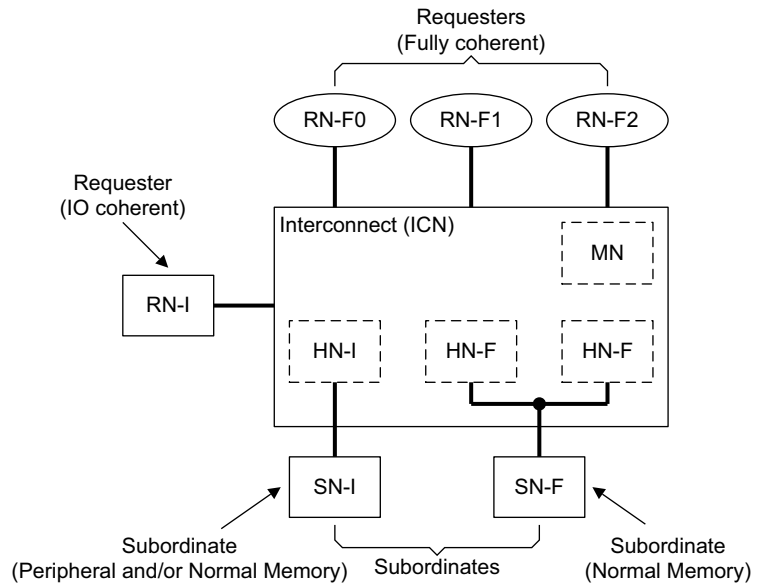

Figure 1-4 Protocol node examples

1.7 Read data source

In a CHI-based system, a Read request can obtain data from different sources. Figure 1-5 shows that these sources are:

- Cache within the interconnect
- Subordinate Node
- Peer RN-F

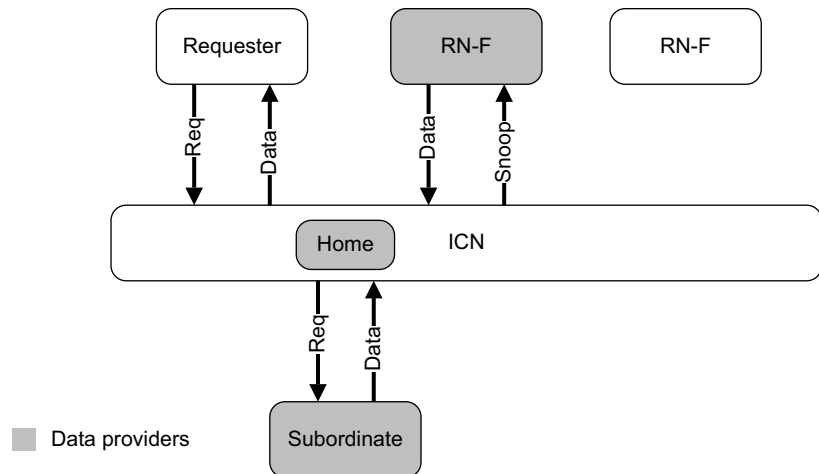

Figure 1-5 Possible Data providers for a Read request

One option for Home is to request that the RN-F or Subordinate Node returns data only to Home. The Home in turn forwards a copy of the received data to the Requester. A hop in obtaining Data in this Read transaction flow can be removed if the Data provider is enabled to forward the Data response directly to the Requester instead of via the Home.

This specification uses several techniques to reduce the number of hops to complete a transaction. This reduction in the number of hops results in Read and Write latency savings as well as reduction in interconnect bandwidth utilization. The techniques can be categorized as:

Direct Memory Transfer (DMT)

Defines the feature that permits the Subordinate Node to send data directly to the Requester.

Direct Cache Transfer (DCT)

Defines the feature which permits a peer RN-F to send data directly to the Requester.

The Data provider in the DCT Read transaction flows has to inform the Home that it has sent Data to the Requester and, in some cases, it also has to send a copy of data to the Home.

Direct Write-data Transfer (DWT)

Defines the feature which permits the requesting Request Node to send write data directly to the Subordinate Node.

Chapter 2

Transactions

This chapter gives an overview of the communication channels between nodes, the associated packet fields, and the transaction structure. It contains the following sections:

- [*Channels overview on page 2-38*](#)
- [*Channel fields on page 2-39*](#)
- [*Transaction structure on page 2-46*](#)
- [*Transaction identifier fields on page 2-93*](#)
- [*Transaction identifier field flows on page 2-100*](#)
- [*Ordering on page 2-121*](#)
- [*Address, Control, and Data on page 2-133*](#)
- [*Data transfer on page 2-142*](#)
- [*Request Retry on page 2-154*](#)

2.1 Channels overview

This section uses shorthand naming for the channels to describe the transaction structure. [Table 2-1](#) shows the shorthand name and the physical channel name that exists on the Request Node or Subordinate Node component.

Communication between nodes is channel-based. [Table 2-1](#) shows the channel naming and the channel designations at the Request Nodes and Subordinate Nodes.

See [Channel on page 13-405](#) for the mapping of physical channels on the Request Node and Subordinate Node components.

Table 2-1 Channel naming and designation at the RN and SN nodes

Channel	RN channel designation	SN channel designation
REQ	TXREQ. Outbound Request.	RXREQ. Inbound Request.
WDAT	TXDAT. Outbound Data. Used for write data, atomic data, snoop data, forward data.	RXDAT. Inbound Data. Used for write data, atomic data.
SRSP	TXRSP. Outbound Response. Used for snoop response and completion acknowledge.	-
CRSP	RXRSP. Inbound Response. Used for responses from the Completer.	TXRSP. Outbound Response. Used for responses from the Completer.
RDAT	RXDAT. Inbound Data. Used for read data, atomic data.	TXDAT. Outbound Data. Used for read data, atomic data.
SNP	RXSNP. Inbound Snoop request.	-

2.2 Channel fields

This section gives a brief overview of the channel fields and indicates which fields affect the transaction structure. The fields associated with each channel are described in the following sections:

- [Transaction request fields](#)
- [Snoop request fields on page 2-43](#)
- [Data fields on page 2-44](#)
- [Response fields on page 2-42](#)

The term ‘transaction structure’ is used to describe the different packets that form a transaction. The transaction structure can vary depending on several factors.

2.2.1 Transaction request fields

[Table 2-2](#) shows the Request fields associated with a Request packet.

More information on the different transaction structures can be found in [Transaction structure on page 2-46](#) and [Flit packet definitions on page 13-418](#).

Table 2-2 Request channel fields

Field	Affects structure	Description
QoS	No	Quality of Service priority. Specifies one of 16 possible priority levels for the transaction with ascending values of QoS indicating higher priority levels. See Chapter 10 Quality of Service .
TgtID	No	Target ID. The node ID of the port on the component to which the packet is targeted. See Target Identifier, TgtID, and Source Identifier, SrcID on page 2-93 and System Address Map, SAM on page 3-160 .
SrcID	No	Source ID. The node ID of the port on the component from which the packet was sent. See Target Identifier, TgtID, and Source Identifier, SrcID on page 2-93 .
TxnID	No	Transaction ID. A transaction has a unique transaction ID per source node. See Transaction Identifier, TxnID on page 2-93 .
ReturnNID	No	Return Node ID. The recipient node ID for the Data response, Persist response, or TagMatch response See Return Node Identifier, ReturnNID on page 2-96 .
StashNID	No	Stash Node ID. The node ID of the Stash target. See Stash Node Identifier, StashNID on page 2-96 .
SLCRepHint	No	System Level Cache Replacement Hint. Forwards cache replacement hints from the Requesters to the caches in the interconnect. See SLC replacement hint on page 11-371 .
StashNIDValid	Yes	Stash Node ID Valid. Indicates that the StashNID field has a valid Stash target value. See Stash Node Identifier Valid, StashNIDValid on page 13-427 .
Endian	No	Endianness. Indicates the endianness of data in the data packet for Atomic transactions. See Endianness on page 2-147 .
Deep	No	Deep persistence. Indicates that the Persist response must not be sent until all earlier writes are written to the final destination. See Deep Persistent CMO on page 4-183 .

Table 2-2 Request channel fields (continued)

Field	Affects structure	Description
ReturnTxnID	No	Return Transaction ID. The unique transaction ID that conveys the value of TxnID in the data response from the Subordinate. See Return Transaction Identifier , ReturnTxnID on page 2-95.
StashLPIDValid	No	Stash Logical Processor ID Valid. Indicates that the StashLPID field value must be considered as the Stash target. See Stash Logical Processor Identifier Valid , StashLPIDValid on page 13-427.
StashLPID	No	Stash Logical Processor ID. The ID of the logical processor at the Stash target. See Stash Logical Processor Identifier , StashLPID on page 13-427.
Opcode	Yes	Request opcode. Specifies the transaction type and is the primary field that determines the transaction structure. See Request types on page 4-172 and REQ channel opcodes on page 13-429.
Size	Yes	Data size. Specifies the size of the data associated with the transaction. This determines the number of data packets within the transaction. See Data transfer on page 2-142.
Addr	No	Address. The address of the memory location being accessed for Read and Write requests. See Address on page 2-133 and Address , Addr on page 13-435.
NS	No	Non-secure. Determines if the transaction is Non-secure or Secure. See Non-secure bit on page 2-133 and Non-secure , NS on page 13-435.
LikelyShared	No	Likely Shared. Provides an allocation hint for downstream caches. See Likely Shared on page 2-139.
AllowRetry	Yes	Allow Retry. Determines if the target is permitted to give a Retry response. See Request Retry on page 2-154.
Order	Yes	Order requirement. Determines the ordering requirement for this request with respect to other requests from the same agent. See Ordering on page 2-121.
PCrdType	No	Protocol Credit Type. Indicates the type of Protocol Credit being used by a request that has the AllowRetry field deasserted. See Request Retry on page 2-154.
MemAttr	No	Memory attribute. Determines the memory attributes associated with the transaction. See Memory Attributes on page 2-134.
SnprAttr	No	Snoop attribute. Specifies the snoop attributes associated with the transaction. See Snoop Attribute , SnprAttr on page 2-139.
DoDWT	Yes	Do Direct Write Transfer. Supports Direct Write-data Transfer and the handling of Combined Writes. See Do Direct Write Transfer , DoDWT on page 13-438.
LPID	No	Logical Processor ID. Used with the SrcID field to uniquely identify the logical processor that generated the request. See Logical Processor Identifier , LPID on page 13-426.
PGroupID	No	Persistence Group ID. Indicates the set of CleanSharedPersistSep transactions to which the request applies. See Persistence Group Identifier , PGroupID on page 13-426.
StashGroupID	No	Stash Group ID. Indicates the set of StashOnceSep transactions to which the request applies. See Stash Group Identifier , StashGroupID on page 13-427.

Table 2-2 Request channel fields (continued)

Field	Affects structure	Description
TagGroupID	No	TagGroupID. Precise contents are IMPLEMENTATION DEFINED. Typically expected to contain Exception level, TTBR value, and CPU identifier. See Tag Group Identifier, TagGroupID on page 13-443
Excl	No	Exclusive access. Indicates that the corresponding transaction is an Exclusive access transaction. See Chapter 6 Exclusive accesses .
SnoopMe	No	Snoop Me. Indicates that Home must determine whether to send a snoop to the Requester during an Atomic transaction. See Atomic transactions on page 2-74.
ExpCompAck	Yes	Expect CompAck. Indicates that the transaction will include a completion acknowledge message. See Transaction structure on page 2-46 and Ordering on page 2-121.
TagOp	Yes	Tag Operation. Indicates the operation to be performed on the tags present in the corresponding DAT channel. See Tag Operation, TagOp on page 13-443.
TraceTag	No	Trace Tag. Provides extra support for the debugging, tracing, and performance measurement of systems. See Chapter 11 System Debug, Trace, and Monitoring .
MPAM	No	Memory System Performance Resource Partitioning and Monitoring. Efficiently utilizes the memory resources among users and monitors their use. See MPAM on page 11-373.
RSVDC	No	User-defined. See Reserved for Customer Use, RSVDC on page 13-449.

2.2.2 Response fields

Table 2-3 describes the fields associated with a Response packet.

Table 2-3 Response packet fields

Field	Description
QoS	Quality of Service priority. As defined in <i>Request channel fields</i> on page 2-39. See <i>Chapter 10 Quality of Service</i> .
TgtID	Target ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Target Identifier; TgtID, and Source Identifier; SrcID</i> on page 2-93.
SrcID	Source ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Target Identifier; TgtID, and Source Identifier; SrcID</i> on page 2-93.
TxnID	Transaction ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Transaction Identifier; TxnID</i> on page 2-93.
Opcode	Response opcode. Specifies the response type. See <i>RSP channel opcodes</i> on page 13-432.
RespErr	Response Error status. As defined in <i>Data packet fields</i> on page 2-44. See <i>Chapter 6 Exclusive accesses</i> and <i>Error response fields</i> on page 9-343.
Resp	Response status. As defined in <i>Data packet fields</i> on page 2-44. See <i>Response types</i> on page 4-208.
FwdState	Forward State. As defined in <i>Data packet fields</i> on page 2-44. See <i>Forward State; FwdState</i> on page 13-446.
DataPull	Data Pull. As defined in <i>Data packet fields</i> on page 2-44. See <i>Snoop requests and Data Pull</i> on page 7-304.
CBusy	Completer Busy. As defined in <i>Data fields</i> on page 2-44. See <i>Completer Busy</i> on page 11-375.
DBID	Data Buffer ID. As defined in <i>Data packet fields</i> on page 2-44. See <i>Data Buffer Identifier; DBID</i> on page 2-94 and <i>Ordering</i> on page 2-121.
PGroupID	Persistence Group ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Persistence Group Identifier; PGroupID</i> on page 13-426.
StashGroupID	Stash Group ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Stash Group Identifier; StashGroupID</i> on page 13-427.
TagGroupID	TagGroupID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Tag Group Identifier; TagGroupID</i> on page 13-443.
PCrdType	Protocol Credit Type. See <i>PCrdType</i> on page 2-156.
TagOp	Tag Operation. As defined in <i>Request channel fields</i> on page 2-39. See <i>Tag Operation; TagOp</i> on page 13-443.
TraceTag	Trace Tag. As defined in <i>Request channel fields</i> on page 2-39. See <i>Chapter 11 System Debug, Trace, and Monitoring</i> .

2.2.3 Snoop request fields

Table 2-4 shows the Snoop request fields. Many of the Snoop request fields are the same as fields defined for the Request channel.

Table 2-4 Snoop request fields

Field	Affects structure	Description
QoS	No	Quality of Service priority. As defined in <i>Request channel fields</i> on page 2-39. See <i>Chapter 10 Quality of Service</i> .
SrcID	No	Source ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Target Identifier, TgtID, and Source Identifier, SrcID</i> on page 2-93.
TxnID	No	Transaction ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Transaction Identifier, TxnID</i> on page 2-93.
FwdNID	No	Forward Node ID. The node ID of the original Requester. See <i>Forward Node Identifier, FwdNID</i> on page 2-98.
FwdTxnID	No	Forward Transaction ID. The transaction ID used in the Request by the original Requester. See <i>Forward Transaction Identifier, FwdTxnID</i> on page 2-95.
StashLPIDValid	No	Stash Logical Processor ID Valid. As defined in <i>Request channel fields</i> on page 2-39. See <i>Stash Logical Processor Identifier Valid, StashLPIDValid</i> on page 13-427.
StashLPID	No	Stash Logical Processor ID. As defined in <i>Request channel fields</i> on page 2-39. See <i>Stash Logical Processor Identifier, StashLPID</i> on page 13-427.
VMIDExt	No	Virtual Machine ID Extension. See <i>DVM Operation types</i> on page 8-323.
Opcode	Yes	Snoop opcode. See <i>Snoop request fields</i> on page 2-43 and <i>SNP channel opcodes</i> on page 13-433.
Addr	No	Address. The address of the memory location being accessed for Snoop requests. See <i>Address</i> on page 2-133 and <i>Address, Addr</i> on page 13-435.
NS	No	Non-secure or Secure access. As defined in <i>Request channel fields</i> on page 2-39. See <i>Non-secure bit</i> on page 2-133 and <i>Non-secure, NS</i> on page 13-435.
DoNotGoToSD	No	Do Not Go To SD state. Controls Snoopee use of SD state. See <i>Do not transition to SD</i> on page 4-252.
RetToSrc	Yes	Return to Source. Instructs the receiver of the snoop to return data with the Snoop response. See <i>Returning Data with Snoop response</i> on page 4-251.
TraceTag	No	Trace Tag. As defined in <i>Request channel fields</i> on page 2-39. See <i>Chapter 11 System Debug, Trace, and Monitoring</i> .
MPAM	No	Memory System Performance Resource Partitioning and Monitoring. As defined in <i>Request channel fields</i> on page 2-39. See <i>MPAM</i> on page 11-373.

———— Note ————

This specification does not define a TgtID field for the Snoop request. See *Target ID determination for snoop request messages* on page 3-164.

2.2.4 Data fields

Table 2-5 describes the fields associated with a Data packet. Data packets can be sent on the RDAT or WDAT channels. The fields in a Data packet do not affect the transaction structure.

Table 2-5 Data packet fields

Field	Description
QoS	Quality of Service priority. As defined in Request channel fields on page 2-39 . See Chapter 10 Quality of Service .
TgtID	Target ID. As defined in Request channel fields on page 2-39 . See Target Identifier, TgtID, and Source Identifier, SrcID on page 2-93 .
SrcID	Source ID. As defined in Request channel fields on page 2-39 . See Target Identifier, TgtID, and Source Identifier, SrcID on page 2-93 .
TxnID	Transaction ID. As defined in Request channel fields on page 2-39 . See Transaction Identifier, TxnID on page 2-93 .
HomeNID	Home Node ID. The node ID of the target of the CompAck response to be sent from the Requester. See Home Node Identifier, HomeNID on page 2-97 .
Opcode	Data opcode. Indicates, for example, if the data packet is related to a Read transaction, a Write transaction, or a Snoop transaction. See DAT channel opcodes on page 13-434 .
RespErr	Response Error status. Indicates the error status associated with a data transfer. See Chapter 6 Exclusive accesses and Error response fields on page 9-343 .
Resp	Response status. Indicates the cache line state associated with a data transfer. See Response types on page 4-208 .
FwdState	Forward State. Indicates the cache line state associated with a data transfer to the Requester from the receiver of the snoop. See Forward State, FwdState on page 13-446 .
DataPull	Data Pull. Indicates the inclusion of an implied Read request in the Data response. See Snoop requests and Data Pull on page 7-304 .
DataSource	Data Source. The value indicates the source of the data in a read Data response. See Data Source indication on page 11-368 .
CBusy	Completer Busy. Indicates the current level of activity at the Completer. See Completer Busy on page 11-375 .
DBID	Data Buffer ID. The ID provided to be used as the TxnID in the response to this message. See Data Buffer Identifier, DBID on page 2-94 and Ordering on page 2-121 .
CCID	Critical Chunk Identifier. Replicates the address offset of the original Transaction request. See Data transfer on page 2-142 .
DataID	Data Identifier. Provides the address offset of the data provided in the packet. See Data transfer on page 2-142 .
TagOp	Tag Operation. As defined in Request channel fields on page 2-39 . See Tag Operation, TagOp on page 13-443 .
Tag	Memory Tag. Provides sets of 4-bit tags, each associated with an aligned 16-byte of data. See Tag on page 13-443 .

Table 2-5 Data packet fields (continued)

Field	Description
TU	Tag Update. Indicates which of the Allocation Tags must be updated. See Tag Update, TU on page 13-443 .
TraceTag	Trace Tag. As defined in Request channel fields on page 2-39 . See Chapter 11 System Debug, Trace, and Monitoring .
RSVDC	User-defined. See Reserved for Customer Use, RSVDC on page 13-449 .
BE	Byte Enable. For a data write, or data provided in response to a snoop, indicates which bytes are valid. See Data transfer on page 2-142 .
Data	Data payload. See Data transfer on page 2-142 .
DataCheck	Data Check. Detects data errors in the DAT packet. See Data Check on page 9-356 .
Poison	Poison. Indicates that a set of data bytes has previously been corrupted. See Poison on page 9-355 .

2.3 Transaction structure

This section describes the ways that a transaction can complete. It shows all the permitted options that can be used by the various components that participate in a transaction.

All transaction types, except PCrdReturn and PrefetchTgt, can have a Retry sequence at the start of the transaction. For ease of presentation, the Retry sequence is described separately, see [Retry on page 2-83](#).

Other independent transactions may need to be performed to complete certain transactions, such as a snoop or memory transaction. These transactions are described separately in the later section, [Home Initiated transactions on page 2-84](#).

Some transactions from Home to Subordinate support the use of a separate ReturnNID and ReturnTxnID field, which allow certain responses to be returned to the original Requester rather than the Home. It is permitted, but not required, for the Home to set the ReturnNID and ReturnTxnID fields, such that they are equal to the SrcID and TxnID. This means all responses are returned to the Home. In this instance, the transaction from Home to Subordinate is considered as if it were an independent transaction. See [Home Initiated transactions on page 2-84](#) for more details.

Some messages in this section are described as Optional. This means that whether or not the particular message is included in the transaction flow is determined by a characteristic of the transaction, typically a field or opcode in the request. This does not mean that the sender of the message can choose whether or not it wishes to send the message.

The term Requester is always used to refer to the original Requester of a transaction in this section. This does not mean an intermediate agent that issues a secondary request to complete the original transaction. The term Requester always refers to a Request Node, RN-F or RN-I.

In this section, an arrow containing multiple message labels within a diagram indicates any one of the messages can be sent in a flow. Requirements of when a particular message can be used in the transaction flow can be derived from elsewhere in the specification.

The flows described in this section are intended to include a complete description of the messages that can be included in a transaction flow. It does not include the following:

- The channel that is used for a particular transaction. This information can be derived from elsewhere in the specification.
- A description of when a transaction can be issued or what the reason is for using a particular transaction.
- A description of which combinations of fields can be used in a request. Request fields are only highlighted when they affect the options for completing a transaction.

Dependencies described in this section use the following approach:

- An implicit dependency exists for each component when it first participates in a transaction sequence. With the exception of the original Requester, any other component must receive a first message associated with a transaction before it can send any subsequent messages for that transaction.
- Where a component sends multiple messages associated with the same transaction, it is assumed that component can send the messages in any order and they can be received in any order, unless an explicit dependency is described.
- Data transfers are shown in the diagrams as a single message. This message can consist of multiple data transfers, see [Data transfer on page 2-142](#) for more details. Where a dependency is described, the dependency is from the first data transfer received, except when it is explicitly stated to be different.
- Where a required or permitted dependency exists in one direction between two components, a dependency in the opposite direction is not permitted. The text in this section only describes the dependency in one direction.
- The amount of detail in a dependency rule is context dependent. In some instances where the source of the dependency and what is dependent is obvious, then the agents are not included.

- For any agent that has one or more outputs:
 - If the agent is the original Requester of the transaction, dependencies are described for each input to that agent.
 - If the agent is not the original Requester of the transaction, dependencies are described for each input to that agent after the first input that agent received. Every output is considered dependent on the first input.
- This section does not describe all dependencies across different transactions, even when they are both to the same address. See [Ordering on page 2-121](#) and [Hazard conditions on page 4-253](#).

The conventions used to describe actions in this section are:

Issues

Used only for the first message in a transaction, for example “The Requester issues a WriteNoSnp request...”.

Sends

A message sent by an agent in a direction away from the Requester.

Sends a downstream

A message relayed by an intermediate agent in a direction away from the Requester, for example “The Home sends a downstream Read request to the Subordinate”.

Returns

A message sent by an agent in a direction towards the Requester.

Provides

A message sent by an agent in response to a snoop, for example “...provides a snoop response”.

Permitted, but not required

The action is neither encouraged nor discouraged, and is compliant in either case.

Not permitted

The action described would cause non-compliance to the specification. For example, “it is not permitted to wait for...before sending...”.

2.3.1 Read transactions

Read transactions are grouped into the following types:

- [Allocating Read](#)
- [Non-allocating Read on page 2-50](#)

Allocating Read

[Figure 2-1 on page 2-48](#) shows the possible transaction flows for an Allocating Read transaction.

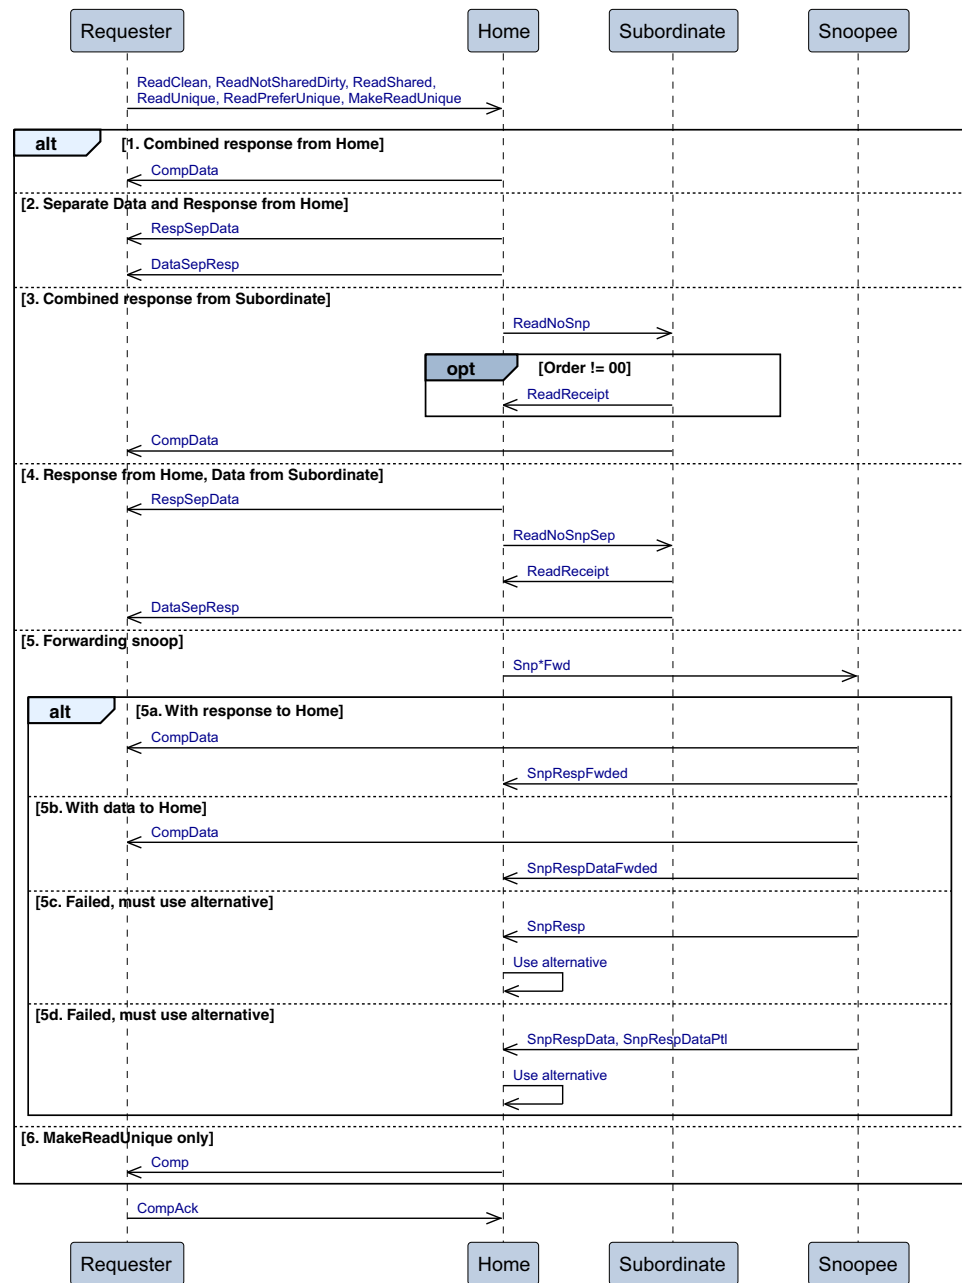

Figure 2-1 Allocating Read

The sequence for the Allocating Read transaction is:

- The transaction starts with the Requester issuing an Allocating Read request to the Home. The initial request is one of the following:
 - ReadClean
 - ReadNotSharedDirty
 - ReadShared
 - ReadUnique
 - ReadPreferUnique
 - MakeReadUnique

- Alternatives 1-6 show different ways that the Home can process the transaction:
 1. **Combined response from Home**
The Home returns a combined response and read data, CompData, to the Requester.
Typically, this option is used by the Home when it can return data and response at the same time. An example is when the data is cached locally.
 2. **Separate data and response from Home**
The Home returns a separate response, RespSepData, and read data, DataSepResp, to the Requester.
Typically, this option is used by the Home when it can return a response quicker than it can provide the data.
 3. **Combined response from Subordinate**
 - The Home sends a downstream read request, ReadNoSnp, to the Subordinate.
 - Optionally, when the Home requests a ReadReceipt response, the Subordinate returns a read receipt, ReadReceipt, to the Home.
 - The Subordinate returns a combined response and read data, CompData, to the Requester.
 Typically, this option is used by the Home either to reduce the message count or reduce design complexity.
 4. **Response from Home, Data from Subordinate**
 - The Home returns a separate response, RespSepData, to the Requester.
 - The Home sends a downstream read data only request, ReadNoSnpSep, to the Subordinate.
 - The Subordinate returns a read receipt, ReadReceipt, to the Home.
It is permitted, but not required, for the Home to wait for ReadReceipt from the Subordinate before sending RespSepData to the Requester.
 - The Subordinate returns read data, DataSepResp, to the Requester.
 Typically, this option is used by the Home when it can return a response quickly, but it does not have the data available and requires the Subordinate to return the data.

———— **Note** ————

In many circumstances, the Requester receives RespSepData far in advance to DataSepResp. The Requester is permitted, but not required, to send the CompAck response after receiving RespSepData without waiting for DataSepResp. The prompt response from the Requester, and potentially receiving ReadReceipt around the same time, permits the Home to complete the transaction faster than when using combined completion and data responses from the Subordinate.

5. **Forwarding snoop**
 - The Home requests a Snoopee to forward read data, Snp*Fwd, to the Requester. See [Request transactions and corresponding Snoop requests on page 4-204](#) to determine which Snp*Fwd transactions can be used.
Typically, this option is used by the Home when the data is not cached locally and it determines that a Snoopee is likely to have a copy.
 - Alternatives 5a-5d show how the Snoopee can process the transaction:
 - Alt 5a. **With response to Home**
 - The Snoopee returns a combined response and read data, CompData, to the Requester.
 - The Snoopee provides a snoop response, SnpRespFwded, to the Home.
 Typically, this option is used by the Snoopee when it can forward data to the Requester and is not required to provide a copy of data to the Home.

Alt 5b. With data to Home

- The Snoopee returns a combined response and read data, CompData, to the Requester.
- The Snoopee provides a snoop response with data, SnpRespDataFwded, to the Home.

———— **Note** ————

Typically, this option is used by the Snoopee when it can forward data to the Requester but it also has to provide a copy of data to the Home. For example, this can happen when the Snoopee holds a Dirty copy of the cache line, but the data returned to the Requester must be Clean. This can also happen when the Home has requested a copy of the data.

Alt 5c. Failed, must use alternative

The Snoopee provides a snoop response, SnpResp, to the Home.

The Home must use another alternative described in this section to complete the transaction to the Requester.

Alt 5d. Failed, must use alternative

The Snoopee provides a snoop response with data, SnpRespData or SnpRespDataPtl, to the Home.

The Home must use another alternative described in this section to complete the transaction to the Requester.

6. MakeReadUnique only

The Home returns a completion response, Comp, to the Requester.

This option is only applicable for a MakeReadUnique transaction when a read data message is not required.

- The transaction ends when the Requester sends a completion acknowledge, CompAck, to the Home.
The CompAck must only be sent after a CompData or RespSepData is received.
It is permitted, but not required, to wait for DataSepResp before sending CompAck.

Non-allocating Read

[Figure 2-2 on page 2-51](#) shows the possible transaction flows for a Non-allocating Read transaction.

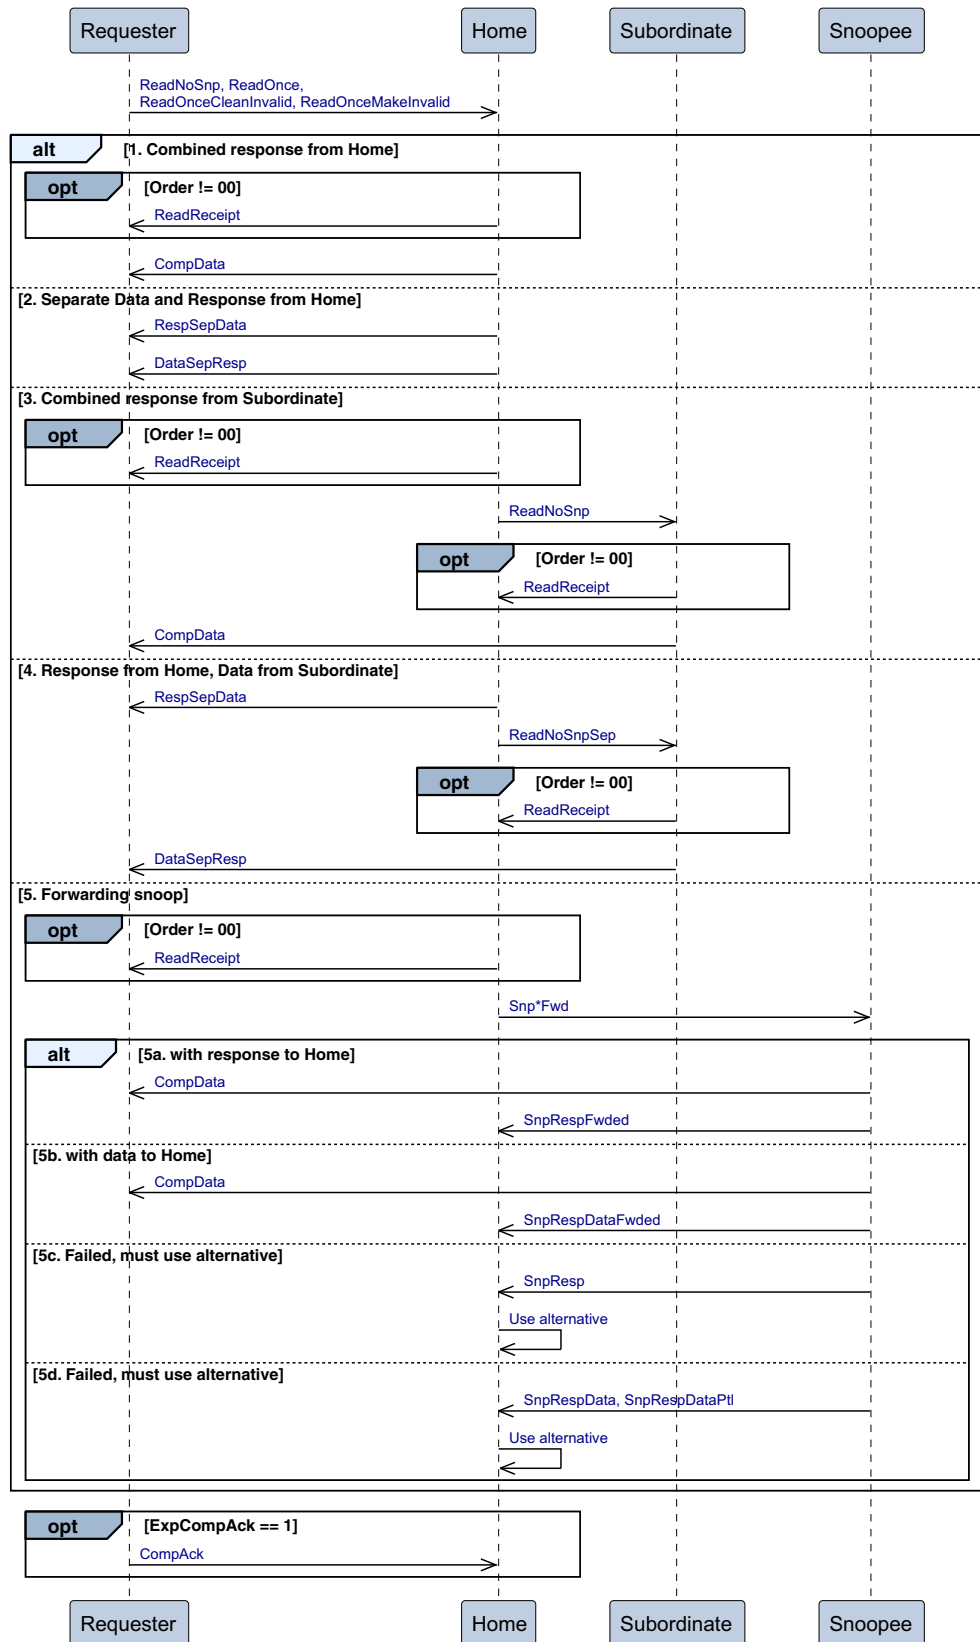

Figure 2-2 Non-allocating Read

The sequence for the Non-allocating Read transactions is:

- The transaction starts with the Requester issuing a Read request to the Home.
The Non-allocating Read transactions are:
 - ReadNoSnp
 - ReadOnce
 - ReadOnceCleanInvalid
 - ReadOnceMakeInvalid
 The request contains the following fields which affect the transaction flow:
 - Order
 - ExpCompAck
- Alternatives, 1-6 show how the Home can process the transaction. For a description of the typical use of the different alternatives, see [Allocating Read on page 2-47](#).
 1. **Combined response from Home**
 - Optionally, when the original request has an ordering requirement, the Home returns a read receipt, ReadReceipt, to the Requester.
 - The Home returns a combined response and read data, CompData, to the Requester.
 2. **Separate data and response from Home**
The Home returns a separate response, RespSepData, and read data, DataSepResp, to the Requester. This alternative cannot be used if the request has an ordering requirement and a completion acknowledge is not required.
 3. **Combined response from Subordinate**
 - Optionally, when the original request has an ordering requirement, the Home returns a read receipt, ReadReceipt, to the Requester.
 - The Home sends a downstream read request, ReadNoSnp, to the Subordinate.
 - Optionally, when the Home requests a ReadReceipt response, the Subordinate returns ReadReceipt to the Home.
The Home must do this when a completion acknowledge is not required.
It is permitted, but not required, for the Home to wait for ReadReceipt from the Subordinate before returning ReadReceipt to the Requester.
 - The Subordinate returns a combined response and read data, CompData, to the Requester.
This alternative cannot be used if the request has an ordering requirement and a completion acknowledge is not required.
 4. **Response from Home, data from Subordinate**
 - The Home returns a separate response, RespSepData, to the Requester and sends a downstream read data only request, ReadNoSnpSep, to the Subordinate.
 - Optionally, when the Home requests a ReadReceipt response, the Subordinate returns a read receipt, ReadReceipt, to the Home. The Home must request a ReadReceipt unless the original request indicates a requirement for both ordering and a completion acknowledge.
It is permitted, but not required, for the Home to wait for ReadReceipt from the Subordinate before returning RespSepData to the Requester.
 - The Subordinate returns read data, DataSepResp, to the Requester.
This alternative cannot be used if the request has an ordering requirement and a completion acknowledge is not required.
 5. **Forwarding snoop**
 - Optionally, when the original request has an ordering requirement, the Home returns a read receipt, ReadReceipt, to the Requester.
 - The Home requests a Snoopee to forward read data, Snp*Fwd, to the Requester.
See [Request transactions and corresponding Snoop requests on page 4-204](#) to determine which Snp*Fwd transactions can be used.

- The alternatives, 5a-5d, show how the Snoopee can process the transaction:
 - Alt 5a. With response to Home**
 - The Snoopee provides a combined response and read data, CompData, to the Requester.
 - The Snoopee provides a snoop response, SnpRespFwded, to the Home.
 - Alt 5b. With data to Home**
 - The Snoopee provides a combined response and read data, CompData, to the Requester.
 - The Snoopee provides a Snoop response with data, SnpRespDataFwded, to the Home.
 - Alt 5c. Failed, must use alternative**
 - The Snoopee provides a snoop response, SnpResp, to the Home.
 - The Home must use another alternative described in this section to complete the transaction to the Requester.
 - Alt 5d. Failed, must use alternative**
 - The Snoopee provides a snoop response with data, SnpRespData or SnpRespDataPtl, to the Home.
 - The Home must use another alternative described in this section to complete the transaction to the Requester.
- If the original request has ExpCompAck asserted, the Requester must only provide a CompAck response after the following:
 - At least one CompData packet is received.
 - RespSepData, if the request does not have an ordering requirement. In this case, it is permitted but not required to wait for DataSepResp.
 - RespSepData and at least one DataSepResp packet, if the request has an ordering requirement.

If the original request has an ordering requirement, it is permitted, but not required, for the Requester to wait for ReadReceipt before sending CompAck.

Table 2-6 lists the permitted DMT and DCT transactions for ReadNoSnp and ReadOnce* from a Request Node. The following key is used:

Y	Yes, permitted
N	No, not permitted
-	The flow is not used in this transaction

Table 2-6 Permitted DMT and DCT for ReadNoSnp and ReadOnce* from an RN

Order [1:0]	ExpCompAck	DMT	DCT	Notes
00	0	Y	Y	Home does not need to be notified of transaction completion. For DMT, Home must obtain a ReadReceipt from Subordinate Node to ensure the request to Subordinate Node is not given a RetryAck response.
	1	Y	Y	When not using DMT, Home does not need to be notified of transaction completion. For DMT, to ensure that the request from the Home to the Subordinate Node is not given a RetryAck response: <ul style="list-style-type: none"> When using ReadNoSnp to the Subordinate Node, Home must either obtain a ReadReceipt from the Subordinate Node or wait for the CompAck response from the Request Node. When using ReadNoSnpSep to the Subordinate Node, Home must obtain a ReadReceipt from the Subordinate Node.
01	-	-	-	Not permitted.
10 11	0	N	Y	For DCT, Home uses the SnpRespFwded or SnpRespDataFwded snoop response to determine transaction completion.
	1	Y	Y	For DMT, Home uses the CompAck response to determine transaction completion. For DCT, Home uses the SnpRespFwd or SnpRespDataFwded snoop response to determine transaction completion.

2.3.2 Write Transactions

Write transactions are grouped into the following types:

- *Immediate write*
- *Write Zero* on page 2-60
- *CopyBack Write* on page 2-61
- *Combined Immediate Write and CMO* on page 2-62
- *Combined Immediate Write and Persist CMO* on page 2-66
- *Combined CopyBack Write and CMO* on page 2-72

Immediate write

Figure 2-3 on page 2-56 shows the possible transaction flows for an Immediate Write transaction.

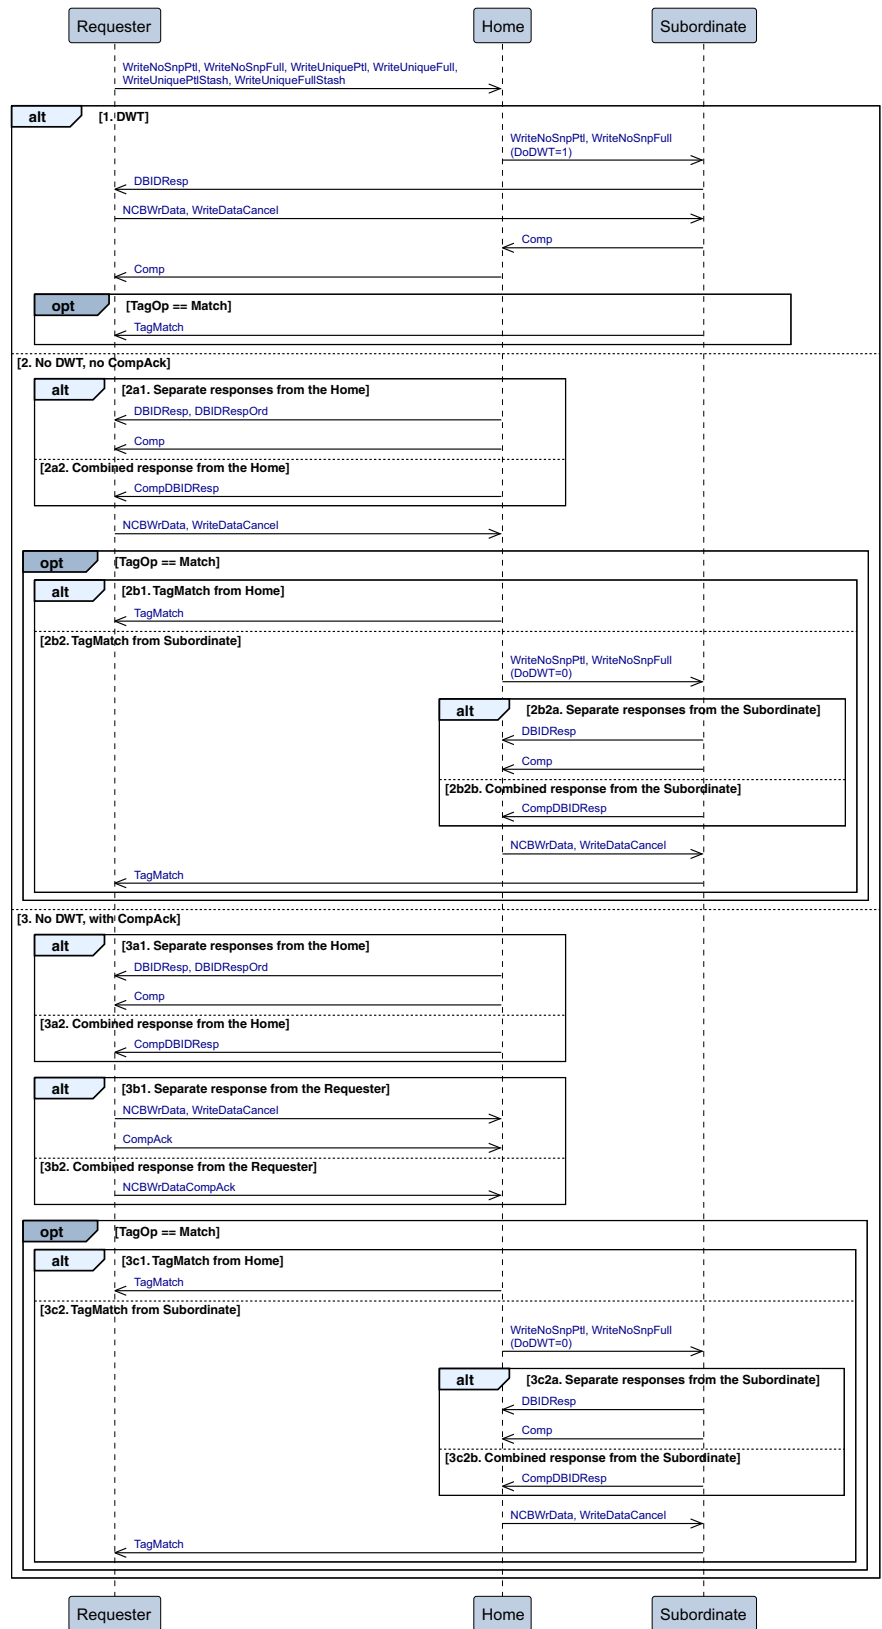

Figure 2-3 Immediate Write

The sequence for Immediate Write transactions is:

- The transaction starts with the Requester issuing an Immediate Write request to the Home.

The Immediate Write transactions are:

- WriteNoSnPtl
- WriteNoSnPFull
- WriteUniquePtl
- WriteUniqueFull
- WriteUniquePtlStash
- WriteUniqueFullStash

Snoop requests that are generated to complete these transactions are considered as independent transactions from the Home and are not shown in this flow. Write requests that are generated to downstream Subordinates, which are not part of the DWT flow, are considered as independent transactions and are not shown in this flow. See [Home Initiated transactions on page 2-84](#) for more details of independent transactions from the Home. Stash snoops that are generated to complete the WriteUniquePtlStash or WriteUniqueFullStash transactions are described in the later section on Stash transactions, see [Stash transactions on page 2-76](#).

The request contains the following fields which affect the transaction flow:

- ExpCompAck
- TagOp

- The Home can choose to complete the transaction using DWT or without DWT. The remainder of the transaction flow will also depend on whether the original request requires a completion acknowledge response, as determined by the ExpCompAck field. The combinations are described in alternatives 1-3:

1. **DWT**

The Home uses DWT.

- The Home sends a downstream write request, WriteNoSnPtl or WriteNoSnPFull, with DoDWT = 1 to the Subordinate.
- The Subordinate returns a data request, DBIDResp, to the Requester.
- The Requester sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.
The Requester must only send this after it has received DBIDResp.
- The Subordinate returns a completion response, Comp, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Requester before returning Comp to the Home.
- The Home returns a completion response, Comp, to the Requester.
It is permitted, but not required, for the Home to wait for Comp from the Subordinate before returning Comp to the Requester.
- Optionally, when the request requires a TagMatch response, the Subordinate returns a tag match response, TagMatch, to the Requester.
It is permitted, but not required, to wait for write data before returning TagMatch.

2. **No DWT, no CompAck**

The Home does not use DWT for a request that does not require a completion acknowledge, CompAck.

- The Home has two alternatives to send the completion response and the data request response to the Requester.

Alt 2a1. Separate responses from the Home

The Home does both the following:

- Returns a data request, DBIDResp or DBIDRespOrd, to the Requester.
- Returns a completion response, Comp, to the Requester.
It is permitted, but not required, to wait for write data before returning Comp.

Alt 2a2. Combined responses from the Home

The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.

- The Requester sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Home. The Requester must only send this after it has received DBIDResp, DBIDRespOrd, or CompDBIDResp.
- Optionally, when the request requires a TagMatch response, the Home has two alternatives.

Alt 2b1. TagMatch from Home

The Home returns a tag match response, TagMatch, to the Requester.

It is permitted, but not required, to wait for write data before returning TagMatch.

Alt 2b2. TagMatch from Subordinate

- The Home sends a downstream write request, WriteNoSnPtl or WriteNoSnPFull, with DoDWT = 0 to the Subordinate. The Subordinate has two alternatives to send return data request and completion response to the Home.

Alt 2b2a. Separate responses from the Subordinate

The Subordinate does both the following:

- Returns data request, DBIDResp, to the Home.
- Returns a completion response, Comp, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Home before returning Comp to the Home.

Alt 2b2b. Combined response from the Subordinate

The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.

- The Home sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.
The Home must only send this after it has received DBIDResp or CompDBIDResp.
- The Subordinate returns a tag match response, TagMatch, to the Requester.
It is permitted, but not required, to wait for write data before returning TagMatch.

3. No DWT, with CompAck

The Home does not use DWT for a request that does require a completion acknowledge, CompAck.

- The Home has two alternatives to return the completion response and the data request response to the Requester.

Alt 3a1. Separate response from the Home

The Home does both the following:

- Returns a data request, DBIDResp or DBIDRespOrd, to the Requester.
- Returns a completion response, Comp, to the Requester.
It is permitted, but not required, to wait for write data before returning Comp.

Alt 3a2. Combined response from the Home

The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.

- The Requester has two alternatives to send write data and completion acknowledge to the Home.

Alt 3b1. Separate response from the Requester

The Requester does both the following:

- Sends write data, NCBWrData, or a write cancellation, WriteDataCancel, to the Home.
The Requester must only send this after it has received DBIDResp, DBIDRespOrd or CompDBIDResp.
- Sends a completion acknowledge, CompAck, to the Home.
The Requester must only send this after it has received Comp or CompDBIDResp.
It is permitted, but not required, to wait for DBIDResp or DBIDRespOrd before sending CompAck.
It is permitted, but not expected, to wait for TagMatch before returning CompAck.

Alt 3b2. Combined response from the Requester

The Requester sends a combined write data and completion acknowledge, NCBWrDataCompAck, to the Home.

The Requester must only send this after it has received CompDBIDResp or both DBIDResp/DBIDRespOrd and Comp.

- Optionally, when the request requires a TagMatch response, the Home has two alternatives to return the response.

Alt 3c1. TagMatch from Home

The Home returns a tag match response, TagMatch, to the Requester.

It is permitted, but not required, to wait for write data before returning TagMatch.

Alt 3c2. TagMatch from Subordinate

- The Home sends a downstream write request, WriteNoSnpPtl or WriteNoSnpFull, with DoDWT = 0 to the Subordinate. The Subordinate has two alternatives to return data request and completion response to the Home.

Alt 3c2a. Separate responses from Subordinate

The Subordinate does both the following:

- Returns a data request, DBIDResp, to the Home.
- Returns a completion response, Comp, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data before sending Comp to the Home.

Alt 3c2b. Combined response from Subordinate

The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.

- The Home sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.
The Home must only send this after it has received DBIDResp or CompDBIDResp.
- The Subordinate returns a tag match response, TagMatch, to the Requester.
It is permitted, but not required, to wait for write data before returning TagMatch.

The Completer of a Write transaction is permitted to return a Comp response as soon as it receives a WriteDataCancel response without dependency on either the processing of the write request or the completion of any snoops sent due to the write.

Write Zero

Figure 2-4 shows the possible transaction flows for a Write Zero transaction.

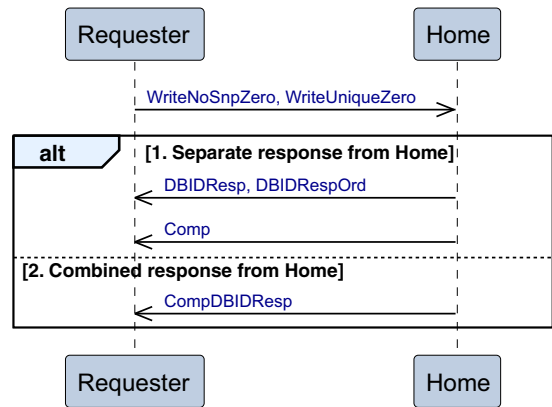

Figure 2-4 Write Zero

- The transaction starts with the Requester issuing a Write Zero request to the Home.
The Write Zero transactions are:
 - WriteUniqueZero
 - WriteNoSnzZero
- The Home has two alternatives to send the completion response and the data request response to the Requester.
 1. **Separate response from Home**
 - The Home returns a data request response, DBIDResp or DBIDRespOrd, to the Requester.
 - The Home returns a completion response, Comp, to the Requester
 2. **Combined response from Home**
The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.

CopyBack Write

Figure 2-5 shows the possible transaction flows for a CopyBack Write transaction.

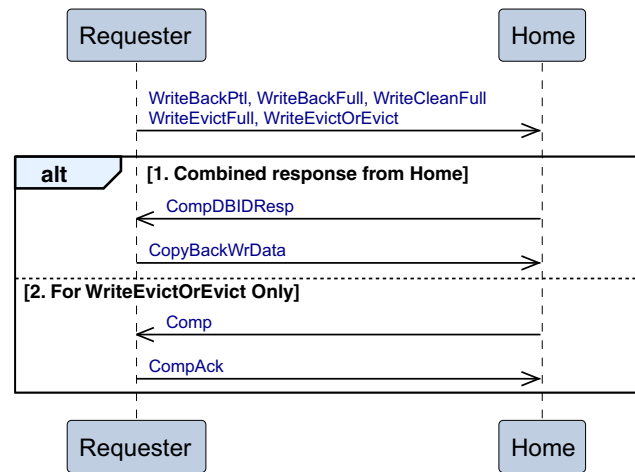

Figure 2-5 CopyBack Write

The sequence for CopyBack Write is:

- The transaction starts with the Requester issuing a CopyBack Write request to the Home.

The CopyBack Write transactions are:

- WriteBackPtl
- WriteBackFull
- WriteCleanFull
- WriteEvictFull
- WriteEvictOrEvict

The request contains the following field which affects the transaction flow:

- Opcode

- The Home can complete any transaction using one of the following alternatives:

1. Combined response from Home

This alternative must be used for:

- WriteBackPtl
- WriteBackFull
- WriteCleanFull
- WriteEvictFull

This alternative can be used for WriteEvictOrEvict transactions.

Typically, it is used for a WriteEvictOrEvict transaction when the Home wants to cache a copy of the cache line.

- The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.
- The Requester sends write data, CopyBackWrData, to the Home.
The Requester must only send this after it has received CompDBIDResp.

2. For WriteEvictOrEvict Only

The Home can complete a WriteEvictOrEvict transaction using the second alternative.

Typically, it is used for a WriteEvictOrEvict transaction when the Home does not want to cache a copy of the cache line.

- The Home returns a completion response, Comp, to the Requester.

- The Requester sends a completion acknowledge, CompAck, to the Home.
The Requester must only send this after it has received Comp.

Combined Immediate Write and CMO

[Figure 2-6 on page 2-63](#) shows the possible transaction flows for a Combined Write and CMO transaction. This only covers Non-persist Cache Maintenance Operations, see [Combined Immediate Write and Persist CMO on page 2-66](#) for transaction flows for a Combined Immediate Write and Persist CMO transaction.

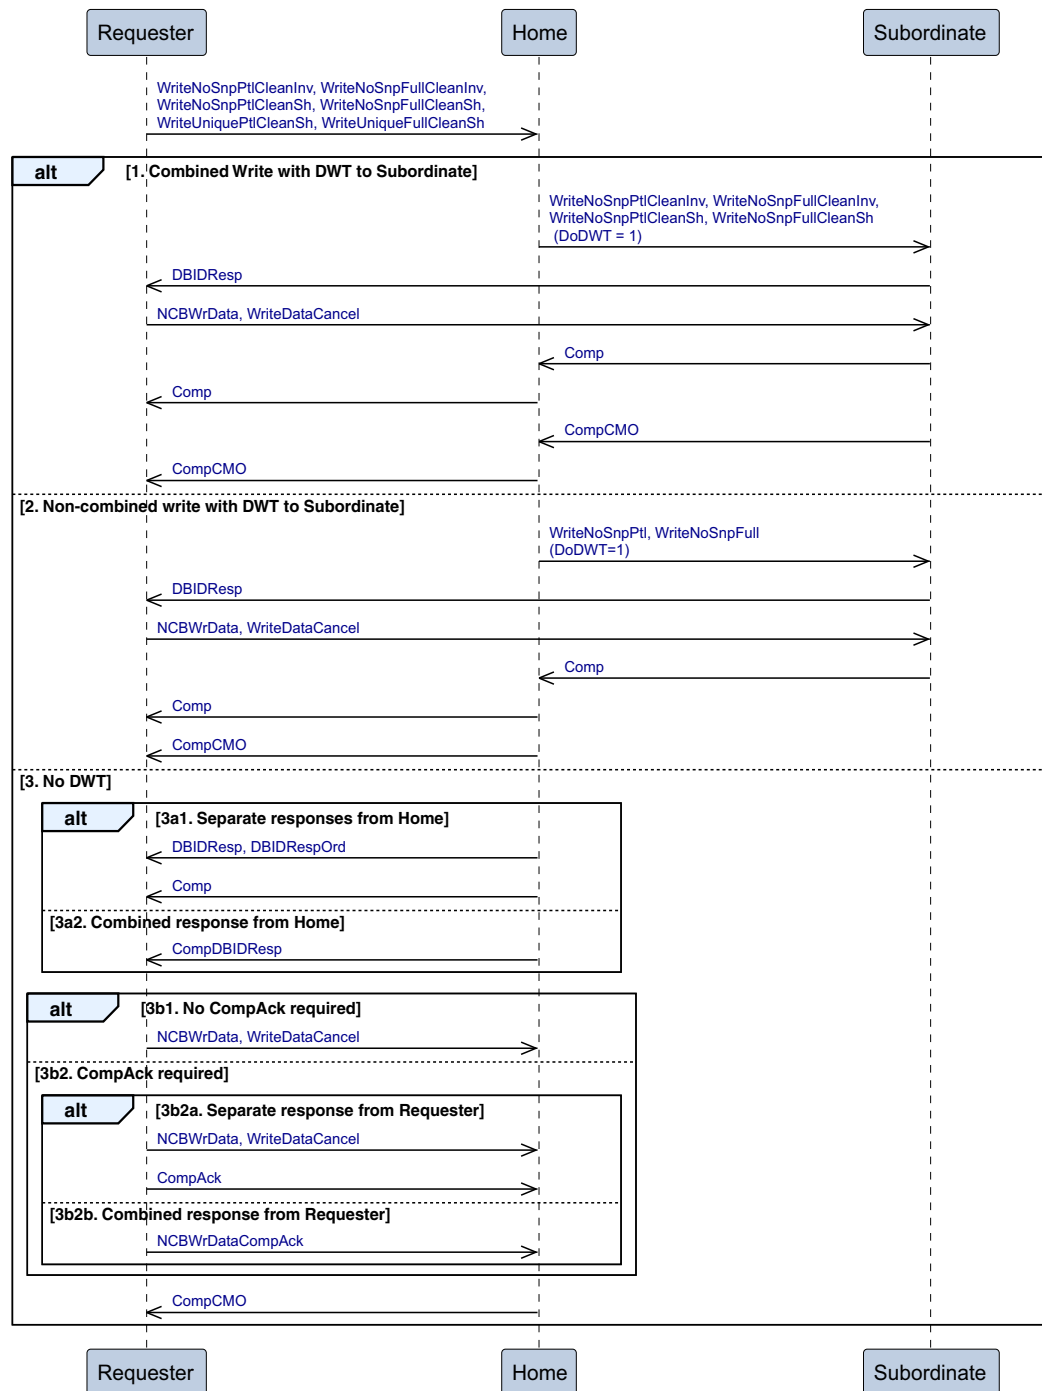

Figure 2-6 Combined Immediate Write and CMO

The sequence for the Combined Immediate Write with CMO transactions is:

- The transaction starts with the Requester issuing a Combined Write and CMO request to the Home.
The Combined Immediate Write and CMO transactions are:
— WriteNoSnpPtlCleanInv

- WriteNoSnpPtlCleanSh
- WriteNoSnpFullCleanInv
- WriteNoSnpFullCleanSh
- WriteUniquePtlCleanSh
- WriteUniqueFullCleanSh

Snoop requests that are generated to complete these transactions are considered as independent transactions from the Home and are not shown in this flow. Write requests that are generated to downstream Subordinates, which are not part of the DWT flow, are considered as independent transactions and are not shown in this flow. Also, CMO requests that only return responses to the Home and are generated to downstream Subordinates are considered independent transactions. See [Home Initiated transactions on page 2-84](#) for more details on independent transactions from the Home. See [Home to Subordinate Write transactions on page 2-85](#) for more details on independent Combined Write and CMO transactions from the Home.

The request contains the following fields which affect the transaction flow:

- Opcode
- ExpCompAck

Note

A TagOp value of Match is not permitted in a Combined Immediate Write and CMO transaction, therefore no TagMatch responses are permitted and the TagOp field does not affect the transaction flow.

The Home has three alternatives to choose from in order to complete the transaction:

- Combined Write with DWT to Subordinate.
- Non-combined Write with DWT to Subordinate.
- Without DWT.

The three approaches are described in the alternatives 1-3.

The remainder of the transaction flow will also depend on whether the original request required a completion acknowledge, as determined by the ExpCompAck.

1. Combined Write with DWT to Subordinate

The Home uses a Combined Write with DWT.

- The Home sends a downstream combined write request with DoDWT = 1 to the Subordinate.
- The Subordinate returns a data request, DBIDResp, to the Requester.
- The Requester sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate. The Requester must only send this after it has received DBIDResp.
- The Subordinate returns a completion response, Comp, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Requester before returning Comp to the Home.
- The Home returns a completion response, Comp, to the Requester.
It is permitted, but not required, for the Home to wait for Comp from the Subordinate before returning Comp to the Requester.
- The Subordinate returns a CMO completion response, CompCMO, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Requester before returning CompCMO to the Home.
- The Home returns a CMO completion response, CompCMO, to the Requester.
It is permitted, but not required, for the Home to wait for Comp or CompCMO from the Subordinate before returning CompCMO to the Requester. If there is an observer downstream of the Home, then the Home must wait for the CompCMO response from the Subordinate before returning CompCMO to the Requester.

2. Non-combined Write with DWT to Subordinate

The Home uses a Non-combined Write with DWT.

- The Home sends a downstream WriteNoSnPtl or WriteNoSnPFull, with DoDWT = 1 to the Subordinate.
- The Subordinate returns a data Request, DBIDResp, to the Requester.
- The Requester sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate. The Requester must only send this after it has received DBIDResp.
- The Subordinate returns a completion response, Comp, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Requester before returning Comp to the Home.
- The Home returns a completion response, Comp, to the Requester.
It is permitted, but not required, for the Home to wait for Comp from the Subordinate before returning Comp to the Requester.
- The Home returns a CMO completion response, CompCMO, to the Requester.
It is permitted, but not required, for the Home to wait for Comp from the Subordinate before returning CompCMO to the Requester.

3. No DWT

The Home does not use DWT.

- The Home has two alternatives to request write data.
 - Alt 3a1. Separate responses from Home**
The Home does both the following:
 - Returns a data request, DBIDResp or DBIDRespOrd, to the Requester.
 - Returns a completion response, Comp, to the Requester.
 It is permitted, but not required, to wait for write data before returning Comp.
 - Alt 3a2. Combined response from Home**
The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.
- The Requester has several alternatives to send write data depending on whether the transaction requires a completion acknowledge.
 - Alt 3b1. No CompAck required**
A completion acknowledge, CompAck, is not required and the Requester sends write data, NCBWrData, or a write cancellation, WriteDataCancel, to the Home.
The Requester must only send this after it has received DBIDResp, DBIDRespOrd or CompDBIDResp.
 - Alt 3b2. Separate response from Requester**
A completion acknowledge is required. The Requester has two alternatives to send write data and completion acknowledge to the Home.
 - Alt 3b2a. Separate response from Requester**
The Requester does both the following:
 - Sends write data, NCBWrData, or a write cancellation, WriteDataCancel, to the Home.
The Requester must only send this after it has received DBIDResp, DBIDRespOrd, or CompDBIDResp.
 - Sends CompAck to the Home.
The Requester must only send this after it has received Comp or CompDBIDResp.
 It is not permitted to wait for CompCMO before sending CompAck.
 - Alt 3b2b. Combined response from Requester**
The Requester sends a combined write data and completion acknowledge, NCBWrDataCompAck, to the Home.

The Requester must only send this after it has received CompDBIDResp or both DBIDResp/DBIDRespOrd and Comp.

- The Home returns a CMO completion response, CompCMO, to the Requester.
It is permitted, but not required, for the Home to wait for write data from the Requester before returning CompCMO.

Combined Immediate Write and Persist CMO

[Figure 2-7 on page 2-67](#) shows the possible transaction flows for Combined Immediate Write and Persist CMO transaction.

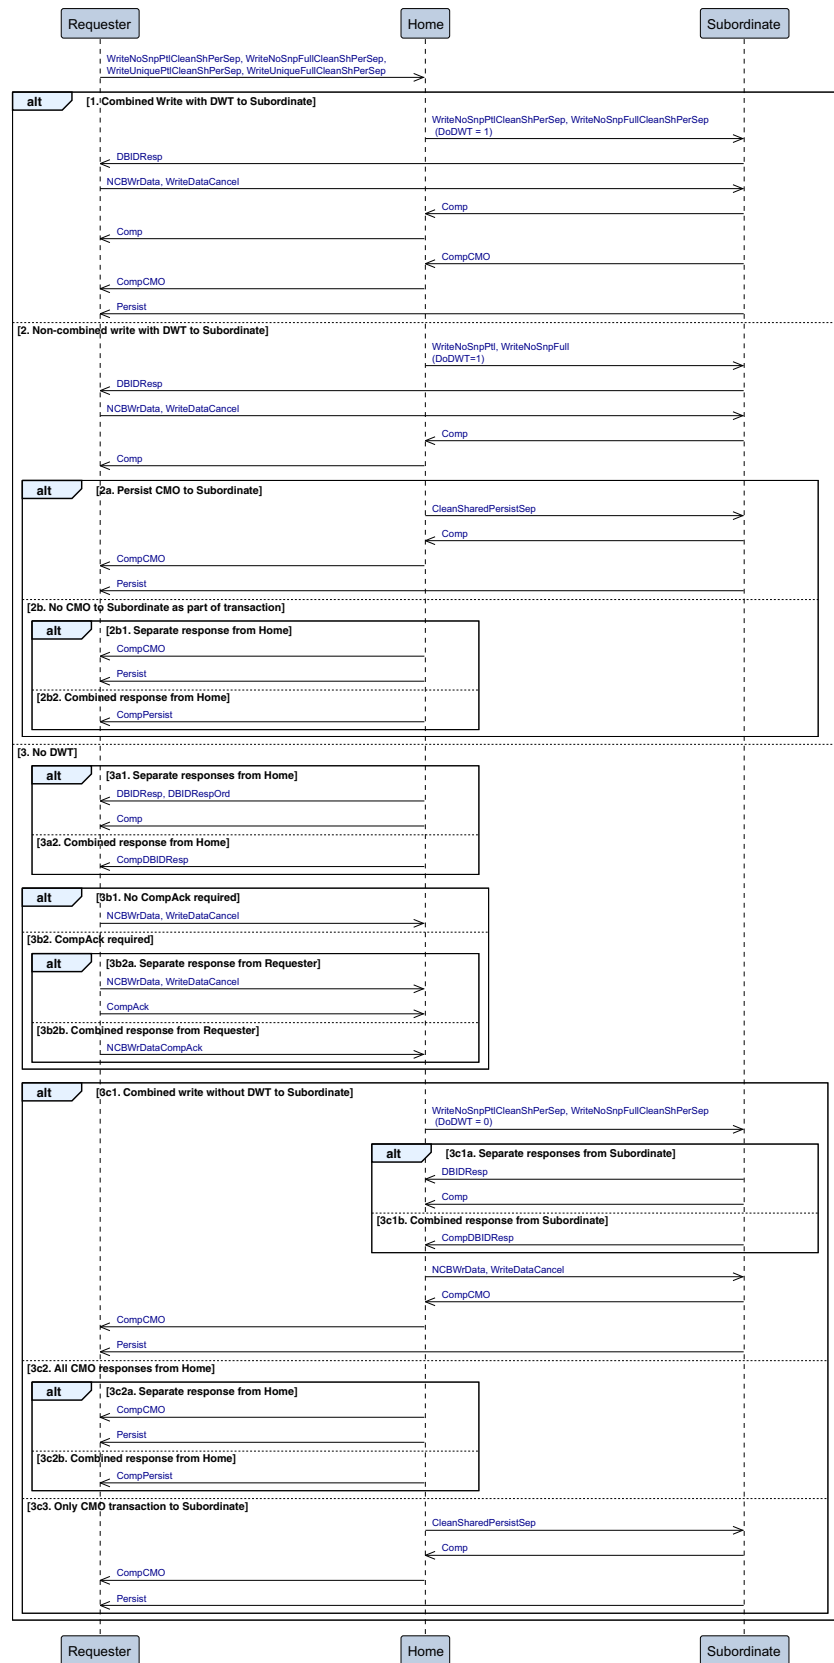

Figure 2-7 Combined Immediate Write and Persist CMO

The sequence for Combined Immediate Write and Persist CMO is:

- The transaction starts with the Requester issuing a Combined Immediate Write and Persist CMO request to the Home.

The Combined Immediate Write and Persist CMO transactions are:

- WriteNoSnpPtlCleanShPerSep
- WriteNoSnpFullCleanShPerSep
- WriteUniquePtlCleanShPerSep
- WriteUniqueFullCleanShPerSep

Snoop requests that are generated to complete these transactions are considered as independent transactions from the Home and are not shown in this flow. Write requests that are generated to downstream Subordinates, which are not part of the DWT flow, are considered as independent transactions and are not shown in this flow. Also, CMO requests that only return responses to the Home and are generated to downstream Subordinates are considered independent transactions. See [Home Initiated transactions on page 2-84](#) for more details on independent transactions from the Home. See [Home to Subordinate Write transactions on page 2-85](#) for more details on independent Combined Write and CMO transactions from the Home.

The request contains the following fields which affect the transaction flow:

- Opcode
- ExpCompAck

Note

A TagOp value of Match is not permitted in a Combined Immediate Write and Persist CMO transaction, therefore no TagMatch responses are permitted and the TagOp field does not affect the transaction flow.

- The Home can choose to complete the transaction using a:
 - Combined Write with DWT to the Subordinate.
 - Non-combined Write with DWT to the Subordinate.
 - Without DWT.

The three approaches are described in alternatives 1-3.

The remainder of the transaction flow will depend on whether the original request required a completion acknowledgment, as determined by the ExpCompAck field.

1. **Combined Write with DWT to Subordinate**

- The Home sends a downstream combined write request with DoDWT = 1 to the Subordinate.
- The Subordinate returns a data request, DBIDResp, to the Requester.
- The Requester sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.
The Requester must only send this after it has received DBIDResp.
- The Subordinate returns a completion response, Comp, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Requester before returning Comp to the Home.
- The Home returns a completion response, Comp, to the Requester.
It is permitted, but not required, for the Home to wait for Comp from the Subordinate before returning Comp to the Requester.
- The Subordinate returns a CMO completion response, CompCMO, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Requester before returning CompCMO to the Home.

- The Home returns a CMO completion response, CompCMO, to the Requester.
It is permitted, but not required, for the Home to wait for Comp or CompCMO from the Subordinate before returning CompCMO to the Requester. If there is an observer downstream of the Home, the Home must wait for the CompCMO response from the Subordinate before returning CompCMO to the Requester.
 - The Subordinate returns a persist response, Persist, to the Requester.
It is permitted, but not required, to wait for write data before returning Persist.
2. **Non-combined write with DWT to Subordinate**
- The Home sends a downstream non-combined write request, WriteNoSnPtl or WriteNoSnPFull, with DoDWT = 1 to the Subordinate.
 - The Subordinate returns a data request, DBIDResp, to the Requester.
 - The Requester sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.
The Requester must only send this after it has received DBIDResp.
 - The Subordinate returns a completion response, Comp, to the Home.
It is permitted, but not required, for the Subordinate to wait for write data from the Requester before returning Comp to the Home.
 - The Home returns a completion response, Comp, to the Requester.
It is permitted, but not required, for the Home to wait for Comp from the Subordinate before returning Comp to the Requester.
 - The Home has two alternatives to send the CMO responses to the Requester.
- Alt 2a. Persist CMO to Subordinate**
- The Home sends a downstream request, CleanSharedPersistSep, to the Subordinate.
 - The Subordinate returns a completion response, Comp, to the Home.
 - The Home returns a CMO completion response, CompCMO, to the Requester.
If there is an observer downstream of the Home, then Home must wait for the Comp response from the Subordinate before returning CompCMO to the Requester.
 - The Subordinate returns a persist response, Persist, to the Requester.
- Alt 2b. No CMO to Subordinate as part of transaction**
The Home sends all the CMO responses to the Requester. The Home has two alternatives to do this.
- Alt 2b1. Separate responses from Home**
The Home does both the following:
- Returns a CMO completion response, CompCMO, to the Requester.
 - Returns a persist response, Persist, to the Requester.
- Alt 2b2. Combined response from Home**
The Home returns a combined completion and persist response, CompPersist, to the Requester.
3. **No DWT**
The Home does not use DWT.
- The Home has two alternatives to request write data.
- Alt 3a1. Separate responses from Home**
The Home does both of the following:
- Returns a data request, DBIDResp or DBIDRespOrd, to the Requester.
 - Returns a completion response, Comp, to the Requester.

It is permitted, but not required, to wait for write data before returning Comp.

Alt 3a2. Combined response from Home

The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.

- The Requester has several alternatives to send write data depending on whether the transaction requires a completion acknowledge.

Alt 3b1. No CompAck required

The Requester sends write data, NCBWrData, or a write cancellation, WriteDataCancel, to the Home.

The Requester must only send this after it has received DBIDResp, DBIDRespOrd, or CompDBIDResp.

Alt 3b2. CompAck required

A completion acknowledge response, CompAck, is required. The Requester has two alternatives to send write data and CompAck to the Home.

Alt 3b2a. Separate response from Requester

The Requester does both the following:

- Sends write data, NCBWrData, or a write cancellation, WriteDataCancel, to the Home.
The Requester must only send this after it has received DBIDResp, DBIDRespOrd, or CompDBIDResp.
- Sends a completion acknowledge, CompAck, to the Home.
The Requester must only send this after it has received Comp or CompDBIDResp.

It is not permitted to wait for CompCMO or Persist before sending CompAck.

Alt 3b2b. Combined response from Requester

The Requester sends a combined write data and completion acknowledge, NCBWrDataCompAck, to the Home.

The Requester must only send this after it has received CompDBIDResp, or both DBIDResp/DBIDRespOrd and Comp.

It is not permitted to wait for CompCMO or Persist before sending NCBWrDataCompAck.

- The Home has several alternatives to complete the remainder of the transaction.

Alt 3c1. Combined Write without DWT to Subordinate

- The Home sends a Combined Write without DWT to the Subordinate.
- The Subordinate has two alternatives to request write data.

Alt 3c1a. Separate responses from Subordinate

The Subordinate does both the following:

- Returns a data request, DBIDResp, to the Home.
- Returns a completion response, Comp, to the Home.
It is permitted, but not required, to wait for write data before returning Comp.

Alt 3c1b. Combined response from Subordinate

The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.

- The Home sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.
The Home must only send this after it has received DBIDResp or CompDBIDResp.

- The Subordinate returns a CMO completion response, CompCMO, to the Home.
It is permitted, but not required, to wait for write data before returning CompCMO.
- The Home returns a CMO completion response, CompCMO, to the Requester.
It is permitted, but not required, for the Home to wait for CompCMO from the Subordinate before returning CompCMO to the Requester.
- The Subordinate returns a persist response, Persist, to the Requester.
It is permitted, but not required, to wait for write data before returning Persist.

Alt 3c2. All CMO transactions from Home

The Home has two alternatives to send all CMO responses to the Requester.

Alt 3c2a. Separate responses from Home

The Home does both the following:

- Returns a CMO completion response, CompCMO, to the Requester.
- Returns a persist response, Persist, to the Requester.

Alt 3c2b. Combined response from Home

The Home returns a combined completion and persist response, CompPersist, to the Requester.

Alt 3c3. Only CMO transactions to Subordinate

- The Home sends a downstream request, CleanSharedPersistSep, to the Subordinate.
Typically, this alternative would only be used where a write to the Subordinate has been previously sent as an independent transaction.
- The Subordinate returns a completion response, Comp, to the Home.
- The Home returns a CMO completion response, CompCMO, to the Requester.
If there is an observer downstream of the Home, then Home must wait for the Comp response from the Subordinate before returning CompCMO to the Requester.
- The Subordinate returns a persist response, Persist, to the Requester.

Combined CopyBack Write and CMO

Figure 2-8 shows the possible transaction flows for a Combined CopyBack Write and CMO transaction.

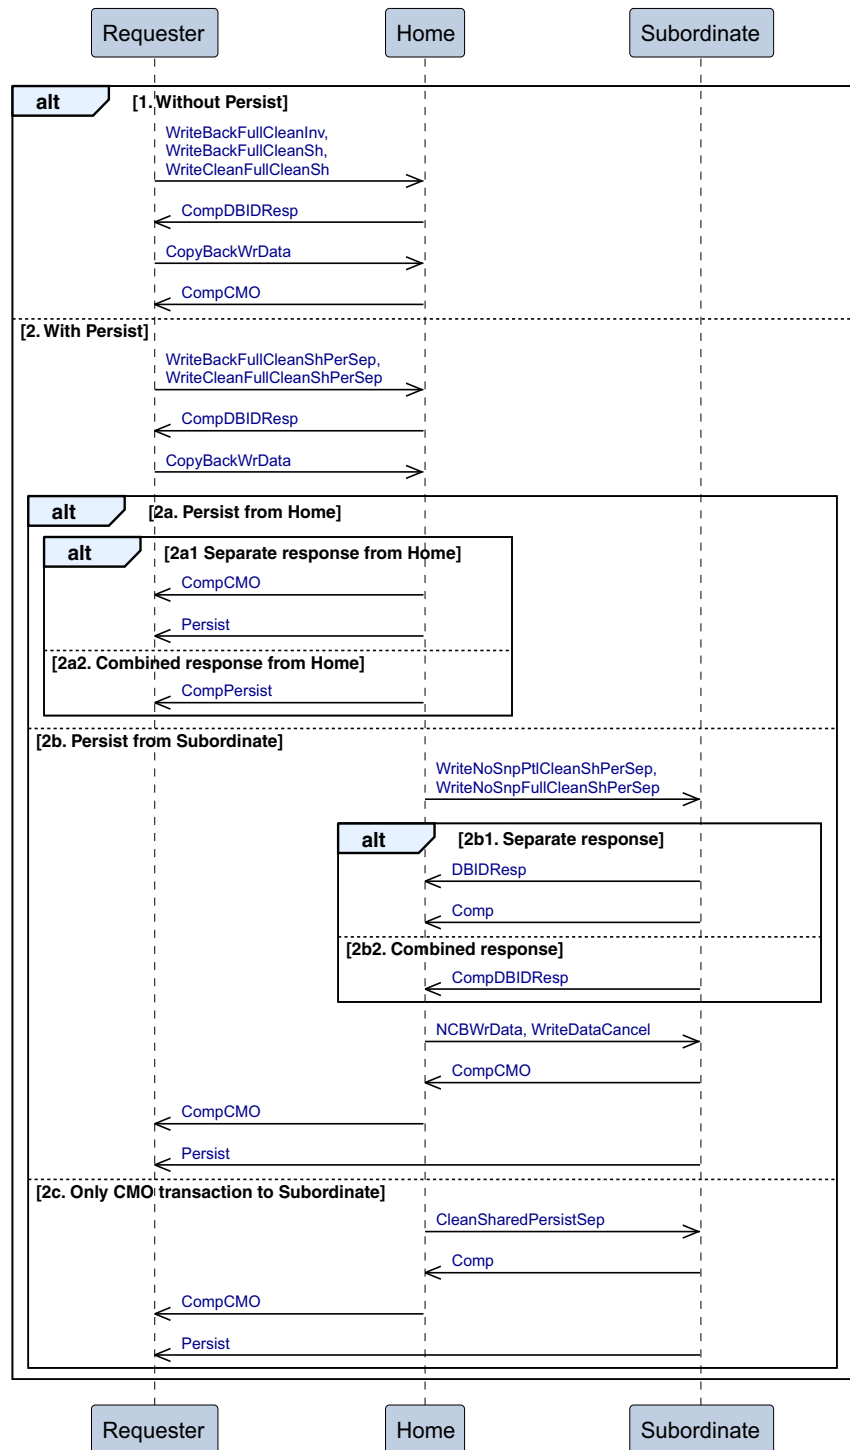

Figure 2-8 Combined CopyBack Write and CMO

There are two possible sequences for Combined CopyBack and CMO transactions.

Write requests that are generated to downstream Subordinates and not part of the DWT or persist flow. These write requests are considered as independent transactions and are not shown in this flow. CMO requests that are generated to downstream Subordinates, which only return responses to the Home, are considered as independent transactions and are not shown in this flow. See [Home Initiated transactions on page 2-84](#) for more details on independent transactions from the Home. See [Home to Subordinate Combined Write and CMO transactions on page 2-87](#) for more details on independent Combined Write and CMO transactions from the Home.

The request contains the following field which affects the transaction flow:

- Opcode

1. Without Persist

The Combined CopyBack Write and CMO transactions without persist are:

- WriteBackFullCleanInv
- WriteBackFullCleanSh
- WriteCleanFullCleanSh

The Requester issues a Combined CopyBack Write and CMO request without Persist response.

- The Requester issues a request to the Home.
- The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.
- The Requester sends write data, CopyBackWrData, to the Home.
The Requester must only send this after it has received CompDBIDResp.
- The Home returns a CMO completion response, CompCMO, to the Requester.
It is permitted, but not required, to wait for write data before returning CompCMO.

2. With Persist

The Combined CopyBack write and CMO transactions are:

- WriteBackFullCleanShPerSep
- WriteCleanFullCleanShPerSep

The Requester issues a Combined CopyBack Write and CMO request with Persist response.

- The Requester issues a request to the Home.
- The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.
- The Requester sends write data, CopyBackWrData, to the Home.
The Requester must only send this after it has received CompDBIDResp.

The Home has three alternatives to complete the transaction, with the persist response either coming from the Home or from the Subordinate.

Alt 2a. Persist from Home

The Home has two alternatives to send the CMO completion response and persist response.

It is permitted, but not required, for the Home to wait for write data before returning CompCMO, Persist, or CompPersist.

Alt 2a1 Separate response from Home

- Returns a CMO completion response, CompCMO, to the Requester.
- Returns a persist response, Persist, to the Requester.

Alt 2a2 Combined response from Home

The Home returns a combined CMO completion response and persist response, CompPersist, to the Requester.

Alt 2b. Persist from Subordinate

When a Combined Write is sent to the Subordinate and the Persist response is returned to the Requester, the following happens:

- The Home sends a downstream write request, WriteNoSnpPtlCleanShPerSep or WriteNoSnpFullCleanShPerSep, to the Subordinate.

It is permitted, but not required, for the Home to wait for write data before sending the downstream write request.

- The Subordinate has two alternatives to return the completion response and the data request response to the Home.

Alt 2b1. Separate response

The Subordinate does both the following:

- Returns a data request, DBIDResp, to the Home.
- Returns a completion response, Comp, to the Home.

It is permitted, but not required, to wait for write data before returning Comp.

Alt 2b2. Combined response

The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.

- The Home sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.

The Home must only send this after it has received DBIDResp or CompDBIDResp.

- The Subordinate returns a CMO completion response, CompCMO, to the Home.

It is permitted, but not required, to wait for write data before returning CompCMO.

- The Home returns a CMO completion response, CompCMO, to the Requester.

It is permitted, but not required, for the Home to wait for CompCMO from the Subordinate before returning CompCMO to the Requester.

- The Subordinate returns a persist response, Persist, to the Requester.

It is permitted, but not required, to wait for write data before returning Persist.

Alt 2c. Only CMO transaction to Subordinate

When a persist CMO is sent to the Subordinate and the Persist response is returned to the Requester, the following happens:

- The Home sends a downstream request, CleanSharedPersistSep, to the Subordinate. Typically, this alternative would only be used where a write to the Subordinate has been previously sent as an independent transaction or the write has been canceled.
- The Subordinate returns a completion response, Comp, to the Home.
- The Home returns a completion response, CompCMO, to the Requester. If there is an observer downstream of the Home, then Home must wait for the Comp response from the Subordinate before returning CompCMO to the Requester.
- The Subordinate returns a persist response, Persist, to the Requester

2.3.3 Atomic transactions

Figure 2-9 on page 2-75 shows the possible transaction flows for an Atomic transaction.

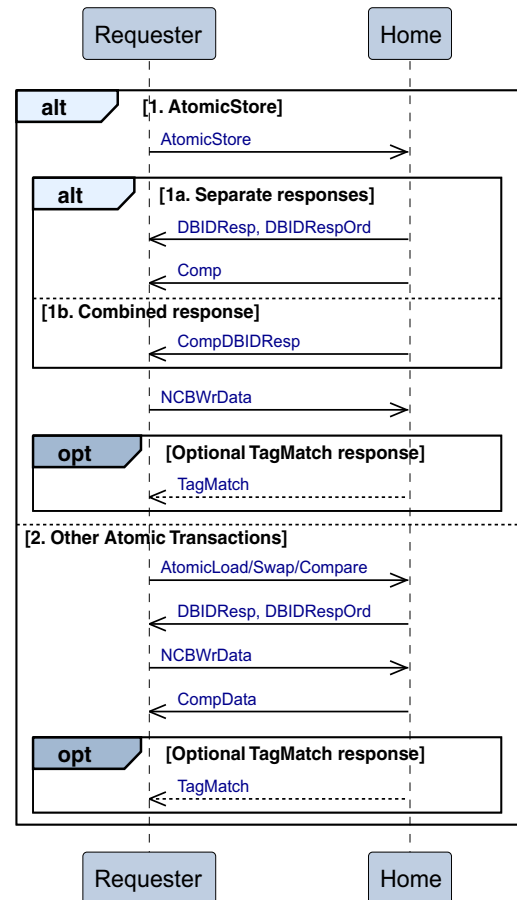

Figure 2-9 Atomic transactions

There are two possible sequences for Atomic transactions.

The Requester alternatives are:

1. AtomicStore

For an AtomicStore transaction:

- The Requester sends an AtomicStore request to the Home.
- The Home has two alternatives to send the completion response and the data request response to the Requester.

Alt 1a. Separate responses

The Home does both the following:

- Returns a data request, DBIDResp or DBIDRespOrd, to the Requester.
- Returns a completion response, Comp, to the Requester.

It is permitted, but not required, to wait for write data before returning Comp.

Alt 1b. Combined response

The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.

- The Requester sends write data, NCBWrData, to the Home.
The Requester must only send this after it has received DBIDResp, DBIDRespOrd, or CompDBIDResp.

- Optionally, when the request requires a TagMatch response, the Home returns a tag match response, TagMatch, to the Requester.
It is permitted, but not required, to wait for write data before returning TagMatch.

2. Other Atomic transactions

For an AtomicLoad, AtomicSwap, or AtomicCompare transaction:

- The Requester sends an AtomicLoad, AtomicSwap, or AtomicCompare request to the Home.
- The Home sends a data request response, DBIDResp or DBIDRespOrd, to the Requester.
- The Requester sends write data, NCBWrData, to the Home.
The Requester must only send this after it has received DBIDResp or DBIDRespOrd. The Requester must not wait to receive CompData before write data is sent.
- The Home returns a combined data and completion response, CompData, to the Requester.
It is permitted, but not required, to wait for write data before returning CompData.
- Optionally, when the request requires a TagMatch response, the Home returns a tag match response, TagMatch, to the Requester.
It is permitted, but not required, to wait for write data before returning TagMatch.

2.3.4 Stash transactions

[Figure 2-10 on page 2-77](#) shows the possible transaction flows for stash transactions.

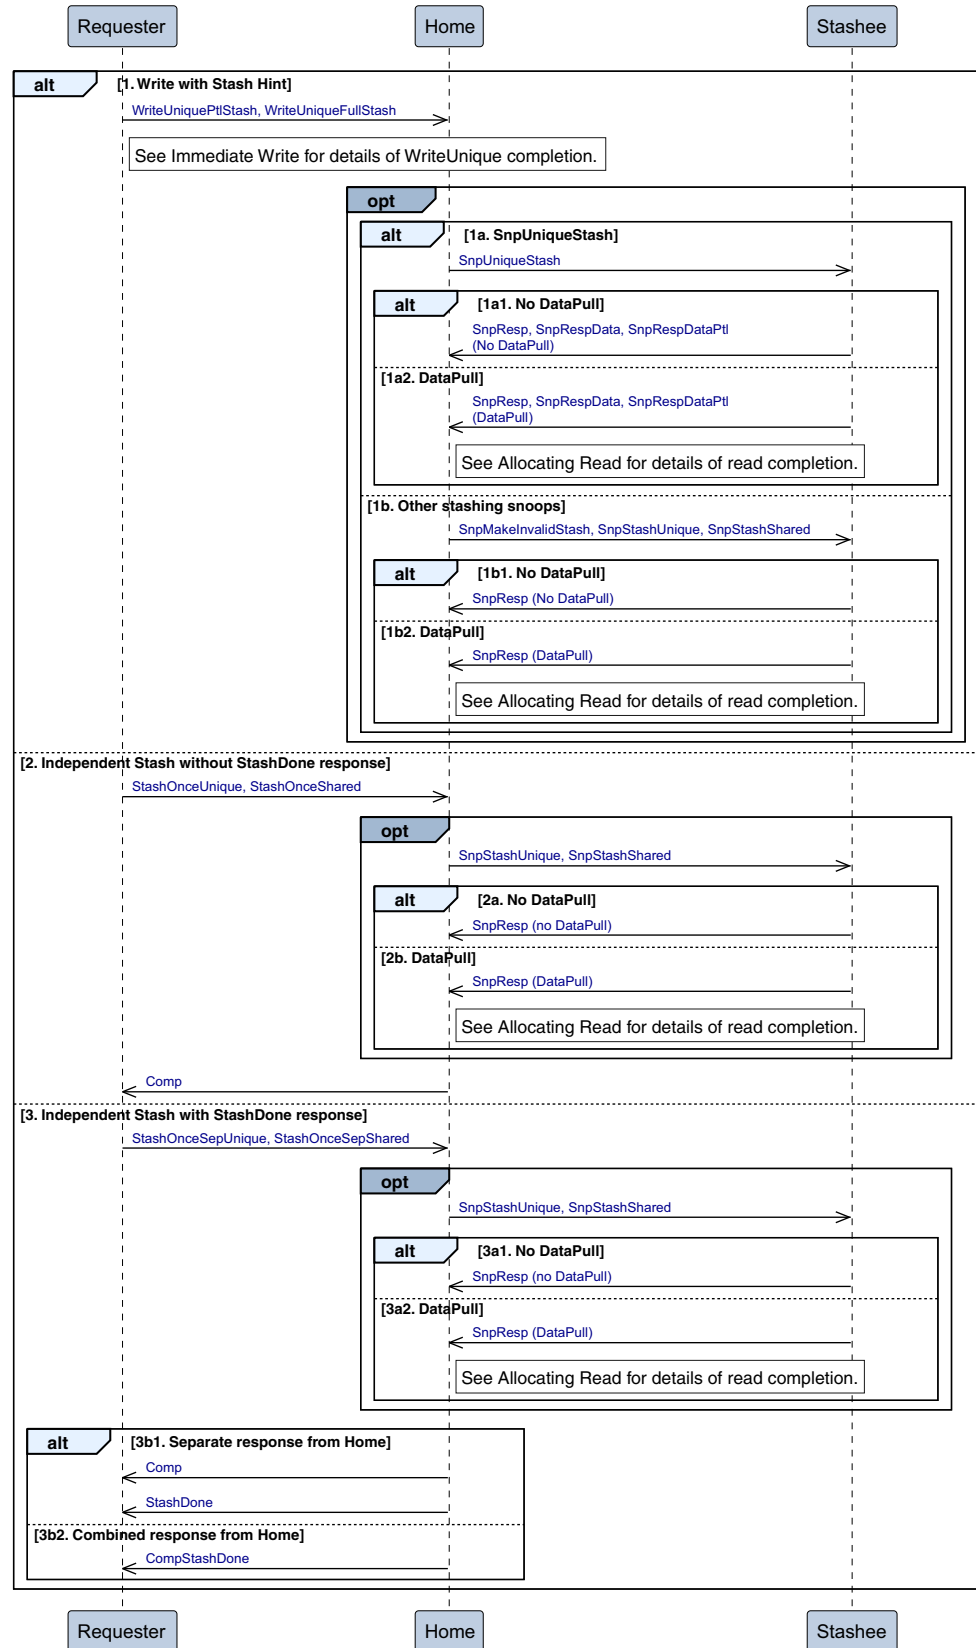

Figure 2-10 Stash transactions

There are three possible sequences for Stash transactions.

The following can affect transaction flow:

- It is permitted for the Home to ignore the Stash request and not perform any stash snoops.
- The Stashee is permitted to ignore the Stash request and not request a data pull to complete the transaction.
- StashOnceSepUnique and StashOnceSepShared can have a separate StashDone response or combined CompStashDone response.

1. Write with Stash Hint

A write with Stash hint starts the transaction. The write with Stash hint requests are:

- WriteUniquePtlStash
- WriteUniqueFullStash

The WriteUnique uses the same transaction flows as an Immediate Write, see [Immediate write on page 2-55](#) for details.

The Home can optionally send a stash snoop request.

Alt 1a. SnpUniqueStash

- The Home sends SnpUniqueStash to the Stashee.
Typically the Home sends SnpUniqueStash for a partial line write. Other snoops, including other stash snoops, are permitted.
- The Stashee has two alternatives to respond to the stash snoop request.

Alt 1a1. No DataPull

Not request a data pull

Alt 1a2. DataPull

Request a data pull.

The completion of a request with data pull is identical to the completion of an Allocating Read transaction, see [Allocating Read on page 2-47](#) for details.

Alt 1b. Other stashing snoops

- Send SnpMakeInvalidStash, SnpStashShared, or SnpStashUnique, to the Stashee.
Typically, the Home sends SnpMakeInvalidStash for a full line write. Other snoops, including other stash snoops, are permitted.
- The Stashee has two alternatives to respond to the stash snoop request.

Alt 1b1. No DataPull

Not request a data pull.

Alt 1b2. DataPull

Request a data pull.

The completion of a request with data pull is identical to the completion of an Allocating Read transaction, see [Allocating Read on page 2-47](#) for details.

2. Independent Stash without StashDone response

An independent Stash without a StashDone response starts the transaction. The independent Stash requests without a StashDone response are:

- StashOnceUnique
- StashOnceShared

The Home can optionally send a stash snoop request, SnpStashUnique or SnpStashShared, to the Stashee.

Typically the Home sends SnpStashUnique when the original request is StashOnceUnique and SnpStashShared when the original request is StashOnceShared.

The Stashee has two alternatives to respond to the stash snoop request.

Alt 2a. No DataPull

Not request a data pull.

Alt 2b. DataPull

Request a data pull.

The completion of a request with data pull is identical to the completion of an Allocating Read transaction, see [Allocating Read on page 2-47](#) for details.

The transaction completes with the Home returning a completion response, Comp, to the original Requester. It is permitted, but not required, to wait for the stash transaction to complete before the Comp response is returned.

3. Independent Stash with StashDone response

An independent Stash with a StashDone response starts the transaction. The independent Stash requests with a StashDone response are:

- StashOnceSepUnique
- StashOnceSepShared

The Home can optionally send a stash snoop request, SnpStashUnique or SnpStashShared, to the Stashee.

Typically the Home sends SnpStashUnique when the original request is StashOnceSepUnique and SnpStashShared when the original request is StashOnceSepShared.

The Stashee has two alternatives to respond to the stash snoop request.

Alt3a1. No DataPull

Not request a data pull.

Alt 3a2. DataPull

Request a data pull.

The completion of a request with data pull is identical to the completion of an Allocating Read transaction, see [Allocating Read on page 2-47](#) for further details.

The Home has two alternatives to complete the transaction.

Alt 3b1. Separate response from Home

The Home does both the following:

- Returns a completion response, Comp, to the Requester.
- Returns a stash done response, StashDone, to the Requester.

Alt 3b2. Combined response from Home

The Home returns a combined completion and stash done response, CompStashDone, to the Requester.

2.3.5 Dataless transactions

Figure 2-11 shows the transaction flow for a Dataless transaction.

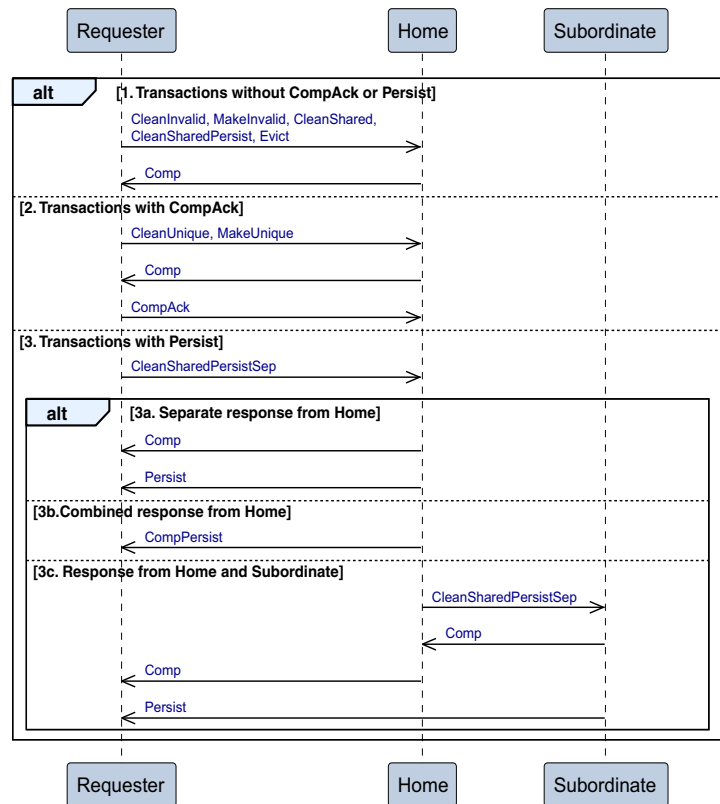

Figure 2-11 Dataless Transactions

There are three possible sequences for Dataless transactions.

1. Transactions without CompAck or Persist

The Dataless transactions without CompAck or Persist are:

- CleanInvalid
- MakeInvalid
- CleanShared
- CleanSharedPersist
- Evict

The Requester sends the request to the Home.

The Home returns a completion response, Comp, to the Requester.

2. Transactions with CompAck

The Dataless transactions with CompAck are:

- CleanUnique
- MakeUnique

The Requester sends the request to the Home.

The Home returns a completion response, Comp, to the Requester.

The Requester sends a completion acknowledge, CompAck, to the Home.

The Requester must only send this after it has received Comp.

3. CleanSharedPersistSep transaction

The Dataless transaction with Persist is:

- CleanSharedPersistSep

The Requester sends the request to the Home.

The Home has three alternatives to complete the transaction.

Alt 3a. Separate responses from the Home

The Home does both the following:

- Returns a completion response, Comp, to the Requester.
- Returns a persist response, Persist, to the Requester.

Alt 3b. Combined response from Home

The Home returns a combined completion and persist response, CompPersist, to the Requester.

Alt 3c. Response from Home and Subordinate

With the Persist response from the Subordinate, the following happens:

- The Home sends a downstream request, CleanSharedPersistSep, to the Subordinate.
- The Subordinate returns a completion response, Comp, to the Home.
- The Home returns a completion response, Comp, to the Requester.
If there is an observer downstream of the Home, the Home must wait for the Comp response from the Subordinate before returning the Comp response to the Requester.
- The Subordinate returns a persist response, Persist, to the Requester

2.3.6 Prefetch transactions

Figure 2-12 shows the transaction flow for a Prefetch transaction.

Figure 2-12 Prefetch Transactions

The sequence for the Prefetch transaction is:

- The Requester sends a PrefetchTgt request directly to the Subordinate.

———— Note ————

No response is given.

2.3.7 DVM transactions

Figure 2-13 shows the transaction flows for a DVM transaction.

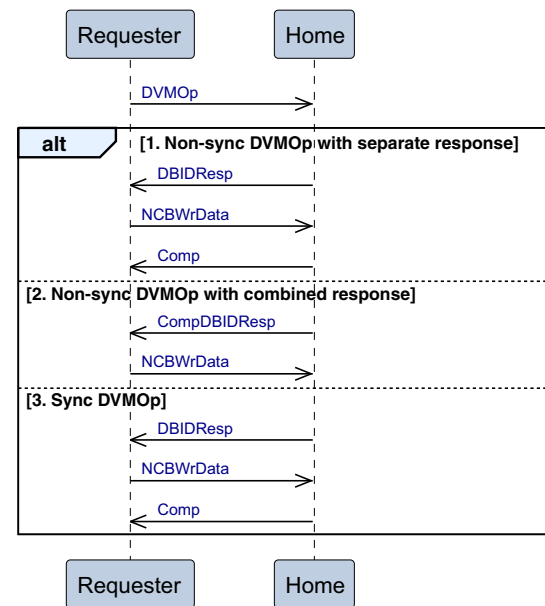

Figure 2-13 DVM Transactions

Snoop requests that are generated to complete a DVM transaction are considered as independent transactions from the Home and are not shown in this flow. See [Home to Snoopee DVM transactions on page 2-92](#) for more details.

The sequence for the DVM transaction is:

- The transaction starts with the Requester issuing a DVMOp request to the Home.
- The Home has three alternatives to send the completion response and the data request response to the Requester.
 1. **Non-sync DVMOp with separate response**
If the DVMOp is a Non-sync DVMOp, the Home can return separate responses.
 - The Home returns a data request, DBIDResp, to the Requester.
 - The Requester sends write data, NCBWrData, to the Home.
The Requester must only send this after it has received DBIDResp.
 - The Home returns a completion response, Comp, to the Requester.
It is permitted, but not required, to wait for write data before returning Comp.
 2. **Non-sync DVMOp with combined response**
If the DVMOp is a Non-sync DVMOp, the Home can return combined responses.
 - The Home returns a combined data request and completion response, CompDBIDResp, to the Requester.
 - The Requester sends write data, NCBWrData, to the Home.
The Requester must only send this after it has received CompDBIDResp.

3. Sync DVMOp

If the DVMOp is a Sync DVMOp, the Home must return separate responses.

- The Home returns a data request, DBIDResp, to the Requester.
- The Requester sends write data, NCBWrData, to the Home.
The Requester must only send this after it has received DBIDResp.
- The Home returns a completion response, Comp, to the Requester.
The Home must only return this after it has received write data.

2.3.8 Retry

Figure 2-14 shows the possible transaction flows for a Retry sequence.

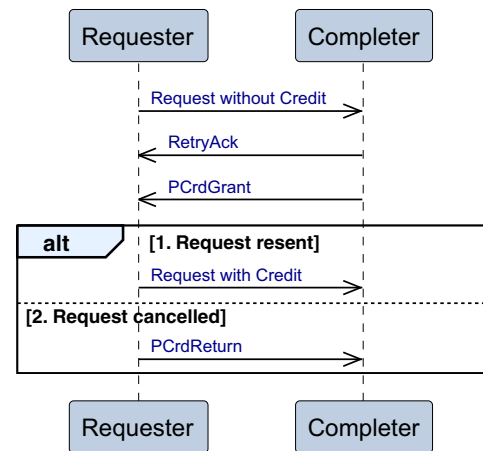

Figure 2-14 Retry Transactions

A request transaction is first sent without a *Protocol Credit* (P-Credit). If the transaction cannot be accepted at the Completer, a *RetryAck* response is given indicating that the transaction is not accepted and can be sent again when an appropriate credit is provided. When the transaction is sent a second time, with a credit, it is guaranteed to be accepted.

The sequence for the Retry transaction is:

- The Requester issues a request without credit.
- The Completer returns a retry response, *RetryAck*, to the Requester.
- The Completer returns a protocol credit grant, *PCrdGrant*, to the Requester.

Typically the protocol credit grant is returned a significant time after the *Retry* response. However, in an atypical case, the *PCrdGrant* response can be returned before the *Retry* response..

- The Requester has two alternatives to conclude the *Retry* sequence. This step must only occur after the Requester has received both *RetryAck* and *PCrdGrant*.

1. Resend the original request

The Requester issues a request with credit.

2. Cancel the request and return the credit

The Requester sends a protocol credit return, *PCrdReturn*, to the Completer.

2.3.9 Home Initiated transactions

The Home Initiated transactions are:

- [Home to Subordinate Read transactions](#)
- [Home to Subordinate Write transactions](#) on page 2-85
- [Home to Subordinate Write Zero transactions](#) on page 2-86
- [Home to Subordinate Combined Write and CMO transactions](#) on page 2-87
- [Home to Subordinate Dataless transactions](#) on page 2-88
- [Home to Subordinate Atomic transactions](#) on page 2-89
- [Home to Snoopee transactions](#) on page 2-91
- [Home to Snoopee DVM transactions](#) on page 2-92

Home to Subordinate Read transactions

Figure 2-15 shows the possible transaction flows for a Home to Subordinate Read transaction.

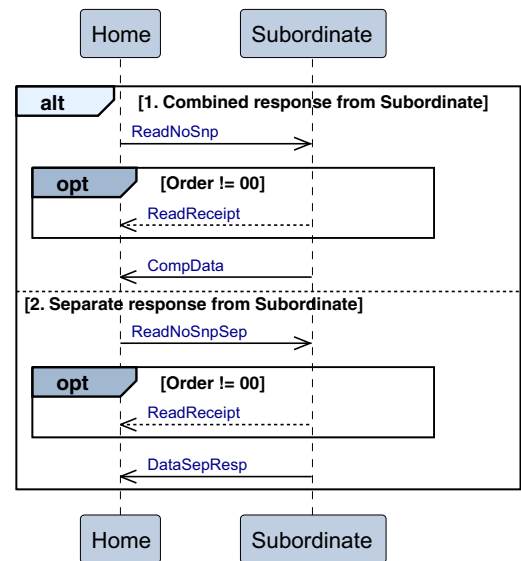

Figure 2-15 Home Read Transactions

The supported transactions are ReadNoSnp and ReadNoSnpSep.

The transaction flow depends on the transaction type.

1. Combined response from Subordinate

- For a ReadNoSnp transaction, the Home issues the request to the Subordinate.
- Optionally, when the request has Order set to non-zero the Subordinate returns a ReadReceipt response.
- The Subordinate returns a combined completion response and read data, CompData, to the Home.

2. Separate responses from Subordinate

- For a ReadNoSnpSep transaction, the Home issues the request to the Subordinate.
- Optionally, when the request has Order set to non-zero, the Subordinate returns a ReadReceipt response.
- The Subordinate returns read data, DataSepResp, to the Home.

Home to Subordinate Write transactions

Figure 2-16 shows the possible transaction flows for a Home to Subordinate Write transaction.

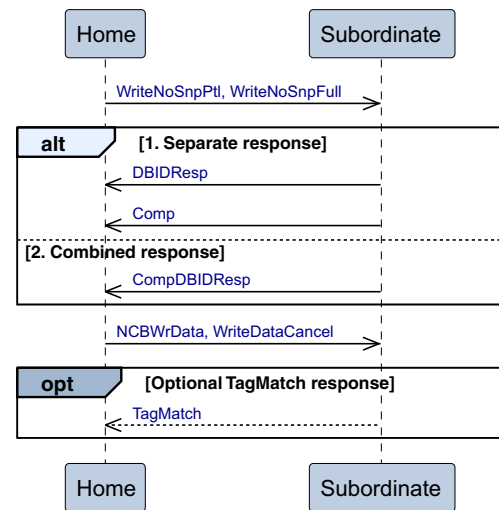

Figure 2-16 Home Write Transactions

The sequence for the Home to Subordinate Write transaction is:

- The transaction starts with the Home issuing a WriteNoSnPtl or WriteNoSnPFull request to the Subordinate.
- The Subordinate has two alternatives to return the completion response and the data request response to the Home.
 1. **Separate response**
The Subordinate does both the following:
 - Returns a Data request response, DBIDResp, to the Home.
 - Returns a completion response, Comp, to the Home.
 It is permitted, but not required, to wait for write data before returning Comp.
 2. **Combined response**
The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.
- The Home sends write data, NCBWrData, or a cancellation, WriteDataCancel to the Subordinate.
The Home must only send this after it has received DBIDResp or CompDBIDResp.
- Optionally, when the request requires a TagMatch response, the Subordinate returns a Tag match response, TagMatch, to the Home.
It is permitted, but not required, to wait for write data before returning TagMatch.

Home to Subordinate Write Zero transactions

Figure 2-17 shows the possible transaction flows for a Home to Subordinate Write Zero transaction.

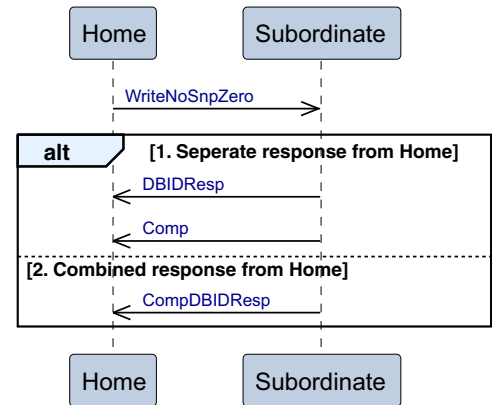

Figure 2-17 Home to Subordinate Write Zero

The sequence for Write Zero is:

- The transaction starts with the Home issuing a Write Zero request to the Subordinate.
The Write Zero transaction is:
— WriteNoSnpZero
- The Subordinate has two alternatives to return the completion response and data request response to the Home.
 1. **Separate response from Home**
The Subordinate does both the following:
 - Returns a data request response, DBIDResp, to the Home.
 - Returns a completion response, Comp, to the Home.
 2. **Combined response from Home**
The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.

Home to Subordinate Combined Write and CMO transactions

Figure 2-18 shows the possible transaction flows for a Home to Subordinate Combined Write and CMO transaction.

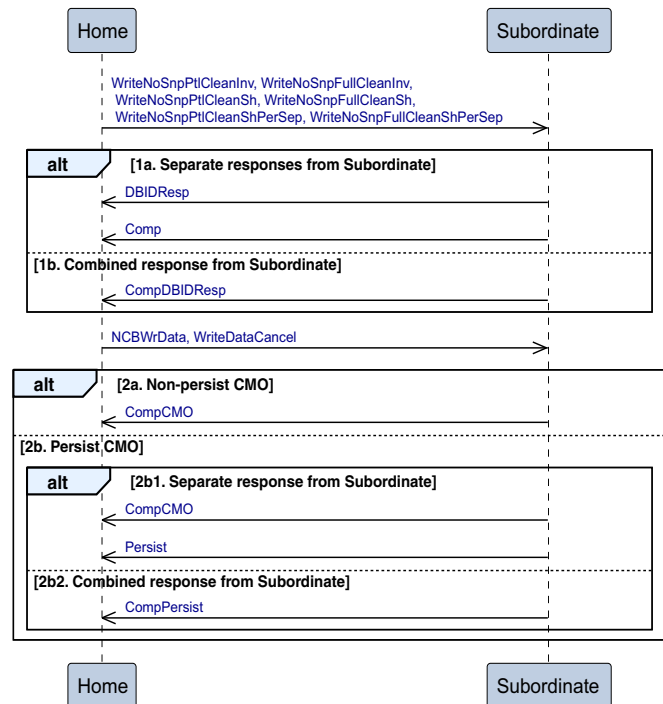

Figure 2-18 Home Combined Write and CMO Transactions

The sequence for the Home to Subordinate Combined Write with CMO transaction is:

- The transaction starts with the Home issuing a Combined Write and CMO request to the Subordinate.
The Home Combined Write and CMO transactions are:
 - WriteNoSnpPtlCleanInv
 - WriteNoSnpFullCleanInv
 - WriteNoSnpPtlCleanSh
 - WriteNoSnpFullCleanSh
 - WriteNoSnpPtlCleanShPerSep
 - WriteNoSnpFullCleanShPerSep
- The Subordinate has two alternatives to send the completion response and the data request response to the Home.
 - Alt 1a. Separate responses from Subordinate**
The Subordinate does both the following:
 - Returns a data request, DBIDResp, to the Home.
 - Returns a completion response, Comp, to the Home.
 It is permitted, but not required, to wait for write data before returning Comp.
 - Alt 1b. Combined response from Subordinate**
The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.
- The Home sends write data, NCBWrData, or a cancellation, WriteDataCancel, to the Subordinate.
The Home must only send this after it has received DBIDResp or CompDBIDResp.

- There are two alternatives for the Subordinate to return the CMO response depending on whether or not a persist response, Persist, is required.

It is permitted, but not required, for the Subordinate to wait for write data before returning CompCMO, Persist, or CompPersist.

Alt 2a. Non-persist CMO

When a persist response is not required, the Subordinate returns a CMO completion response, CompCMO, to the Home.

Alt 2b. Persist CMO

When a persist response is required, the Subordinate has two alternatives to send the CMO completion response and persist response.

Alt 2b1. Separate response from Subordinate

The Subordinate does both the following:

- Returns a CMO completion response, CompCMO, to the Home.
- Returns a persist response, Persist, to the Home.

Alt 2b2. Combined response from Subordinate

The Subordinate returns a combined CMO completion response and persist response, CompPersist, to the Home.

Home to Subordinate Dataless transactions

Figure 2-19 shows the transaction flows for a Home to Subordinate Dataless transaction.

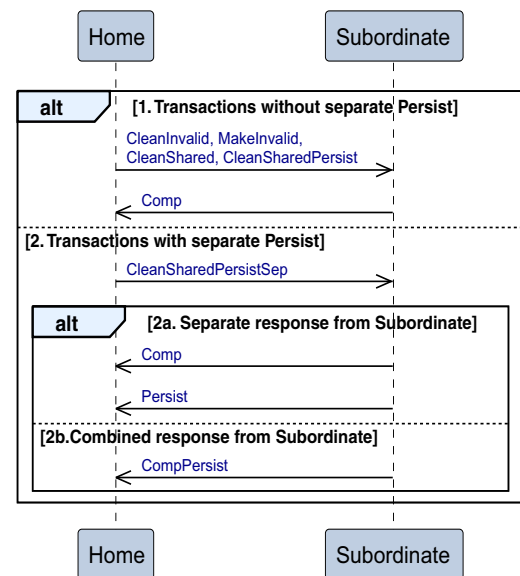

Figure 2-19 Home to Subordinate Dataless Transactions

The transaction flow depends on the request type.

The Home Dataless transactions are:

- CleanInvalid
- MakeInvalid
- CleanShared
- CleanSharedPersist
- CleanSharedPersistSep

The sequence for the Home to Subordinate Dataless transaction is:

- Transactions without separate Persist:**

CleanInvalid, MakeInvalid, CleanShared, or CleanSharedPersist transaction

- The Home sends the request to the Subordinate.
- The Subordinate returns a completion response, Comp, to the Requester.

2. Transactions with separate Persist:

CleanSharedPersistSep transaction

- The Home sends the request to the Subordinate.
- The Subordinate has two alternatives to complete the transaction.

Alt 2a. Separate response from Subordinate

The Subordinate does both the following:

- Returns a completion response, Comp, to the Home.
- Returns a persist response, Persist, to the Home.

Use of separate completion response, Comp, and persist response, Persist, allows a Completer to send an early Comp without waiting for Persist. Typically, Persist takes much longer.

Alt 2b. Combined response from Subordinate

The Subordinate returns a combined completion and persist response, CompPersist, to the Home.

Home to Subordinate Atomic transactions

Figure 2-20 shows the possible transaction flows for a Home to Subordinate Atomic transactions.

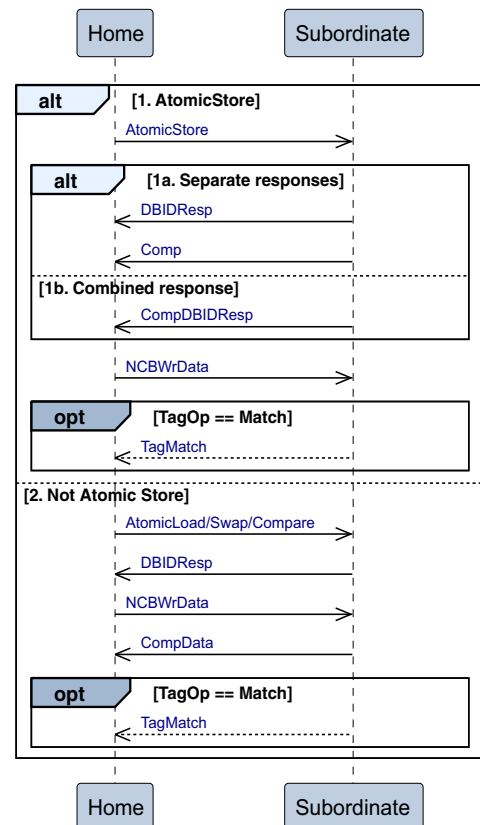

Figure 2-20 Home Atomic transactions

The Atomic transactions the Home can issue are:

- AtomicStore
- AtomicLoad
- AtomicSwap
- AtomicCompare

When the Subordinate supports the execution of atomic operations, the Home is permitted, but not required, to forward Atomic transactions to the Subordinate.

There are two alternatives for the Home to complete the transaction, depending on the request type.

1. **AtomicStore**

- The Home sends an AtomicStore request to the Subordinate.
- The Subordinate has two alternatives to send the completion response and data request response to the Home.

Alt 1a. Separate responses

The Subordinate does both the following:

- Returns a data request, DBIDResp, to the Home.
- Returns a completion response, Comp, to the Home.

It is permitted, but not required, to wait for write data before returning Comp.

Alt 1b. Combined response

The Subordinate returns a combined data request and completion response, CompDBIDResp, to the Home.

- The Home sends write data, NCBWrData, to the Subordinate.
The Home must only send this after it has received DBIDResp or CompDBIDResp. The Home must not wait for Comp before sending write data.
- Optionally, when the request requires a tag match response, the Subordinate returns a TagMatch response to the Home.
It is permitted, but not required, to wait for write data before returning TagMatch.

2. **Not AtomicStore**

- The Home sends an AtomicLoad, AtomicSwap, or AtomicCompare request to the Subordinate.
- The Subordinate sends a data request response, DBIDResp, to the Home.
- The Home sends write data, NCBWrData, to the Subordinate.
The Home must only send this after it has received DBIDResp. The Home must not wait to receive CompData before write data is sent.
- The Subordinate returns a combined data and completion response, CompData, to the Home.
It is permitted, but not required, to wait for write data before returning CompData.
- Optionally, when the request requires a TagMatch response, the Subordinate returns a tag match response, TagMatch, to the Home.
It is permitted, but not required, to wait for write data before returning TagMatch.

Home to Snoopee transactions

Figure 2-21 shows the possible transaction flows for a Home to Snoopee transaction.

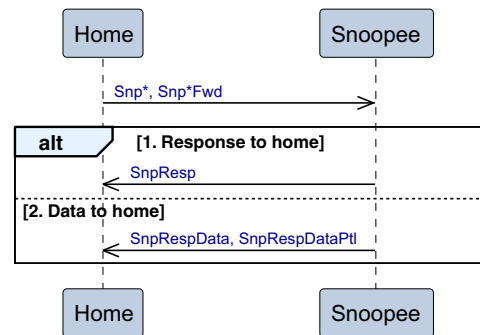

Figure 2-21 Home Snoop Transactions

The following transactions must use this transaction flow.

- SnpOnce
- SnpClean
- SnpNotSharedDirty
- SnpShared
- SnpUnique
- SnpPreferUnique
- SnpCleanShared
- SnpCleanInvalid
- SnpMakeInvalid

The following transactions are also permitted, but not required, to use this transaction flow.

- SnpOnceFwd
- SnpCleanFwd
- SnpNotSharedDirtyFwd
- SnpSharedFwd
- SnpUniqueFwd
- SnpPreferUniqueFwd

The sequence the Home to Snoopee transaction is:

- The transaction starts with the Home issuing a Snoop request to the Snoopee.
- The Snoopee has two alternatives to complete the transaction.
 1. The Snoopee provides a snoop response, SnpResp, to the Home.
This is the only permitted alternative for a SnpMakeInvalid transaction.
 2. The Snoopee provides a snoop response with data, SnpRespData or SnpRespDataPtl.

Home to Snoopee DVM transactions

Figure 2-22 shows the transaction flow for a Home to Snoopee DVM transaction, SnpDVMOp.

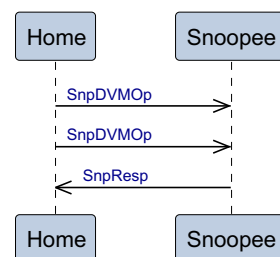

Figure 2-22 Home DVM Snoop

The sequence for the Home to Snoopee DVM transaction is:

- The Home issues two Snoop DVM requests, SnpDVMOp, to the Snoopee.
- The Snoopee provides a single Snoop response, SnpResp.

The Snoopee must only provide the Snoop response after it has received both Snoop DVM requests.

2.4 Transaction identifier fields

Each transaction consists of a number of different packets that are transferred across the interconnect. A set of identifier fields, within a packet, are used to provide additional information about a packet.

The fields that route packets across the interconnect:

- [Target Identifier, TgtID, and Source Identifier, SrcID](#)

The fields that relate all the packets associated with a single transaction are:

- [Transaction Identifier, TxnID](#)
- [Data Buffer Identifier, DBID on page 2-94](#)
- [Return Transaction Identifier, ReturnTxnID on page 2-95](#)
- [Forward Transaction Identifier, FwdTxnID on page 2-95](#)

The field that identifies the individual data packets within a transaction:

- [Data Identifier, DataID, and Critical Chunk Identifier, CCID on page 2-96](#)

The fields that identify individual processing agents within a single Requester:

- [Logical Processor Identifier, LPID on page 2-96](#)
- [Stash Logical Processor Identifier, StashLPID on page 2-96](#)

The field that identifies the target node for a Stash transaction:

- [Stash Node Identifier, StashNID on page 2-96](#)

The field that identifies the recipient node for the Data response, Persist response, or TagMatch response:

- [Return Node Identifier, ReturnNID on page 2-96](#)

The field that identifies the recipient node for the Data response:

- [Forward Node Identifier, FwdNID on page 2-98](#)

The field that is used to identify the recipient node for the CompAck response:

- [Home Node Identifier, HomeNID on page 2-97](#)

The field that is used to identify different sets of transactions:

- [Persistence Group Identifier, PGroupID on page 2-98](#)
- [Stash Group Identifier, StashGroupID on page 2-98](#)
- [Tag Group Identifier, TagGroupID on page 2-99](#)

2.4.1 Target Identifier, TgtID, and Source Identifier, SrcID

A transaction request includes a TgtID that identifies the target node, and a SrcID that identifies the source node. These IDs are used to route packets across the interconnect.

2.4.2 Transaction Identifier, TxnID

A transaction request includes a TxnID that is used to identify the transaction from a given Requester. It is required that the TxnID, except for PrefetchTgt, must be unique for a given Requester. The Requester is identified by the SrcID. This ensures that any returning read data or response information can be associated with the correct transaction.

A 12-bit field is defined for the TxnID with the number of outstanding transactions being limited to 1024. A Requester is permitted to reuse a TxnID value after it has received either:

- All responses associated with a previous transaction that have used the same value.
- A RetryAck response for a previous transaction that used the same value.

[Transaction identifier field flows on page 2-100](#) gives more detailed rules for the different transaction types. The TxnID field is not applicable in a PrefetchTgt request and can take any value.

A value used in the TxnID field of a Request from Home to Subordinate can be reused by Home once all responses that are required to deallocate the request are received or a RetryAck response is received.

A transaction that is retried is not required to use the same TxnID. See [Request Retry](#) on page 2-154.

2.4.3 Data Buffer Identifier, DBID

The DBID field permits the Completer of a transaction to provide its own identifier for a transaction. The Completer sends a response that includes a DBID. The DBID value is used as the TxnID field value in the:

- WriteData response of Immediate Write, CopyBack Write, Combined Write, Atomic, and DVMOp transactions.
- CompData response of Stash transactions for Data Pull purposes.
- CompAck response of Read, Dataless, WriteNoSnp, WriteUnique and Immediate Combined Write transactions that include a CompAck response.

The DBID value used by a Completer in responses of a given transaction must be unique for a given Requester in the following cases:

- DBIDResp or DBIDRespOrd or CompDBIDResp for all Write transactions, except in WriteNoSnpZero and WriteUniqueZero.
- DBIDResp or DBIDRespOrd or CompDBIDResp for all Combined Write transactions.
- DBIDResp or DBIDRespOrd or CompDBIDResp for Atomic transactions.
- DBIDResp or DBIDRespOrd or CompDBIDResp for DVMOp transactions.
- CompData or RespSepData for Read transactions that include CompAck, except in the case when ReadOnce* and ReadNoSnp do not use the resultant CompAck for deallocation of the request at Home.
- Comp for Dataless transactions that include CompAck.

The DBID value is applicable in the DataSepResp response to Read requests that include CompAck and it must be the same as the DBID value in the associated RespSepData response.

A Comp response message sent separate from a DBIDResp or DBIDRespOrd message for a Write or Combined Write transaction must include the same DBID field value in the Comp and DBIDResp or DBIDRespOrd message when the two messages originate from the same source.

A Comp response message sent separate from a DBIDResp or DBIDRespOrd message for a Atomic transaction is permitted, but is not required, to include the same DBID field value in the Comp and DBIDResp or DBIDRespOrd message.

A Completer is permitted, but not required, to use the same DBID value for two transactions with different Requesters. A Completer is permitted to reuse a DBID value after it has received all packets required to deallocate a previous transaction that has used the same value. [Transaction identifier field flows](#) on page 2-100 gives more detailed rules for the different transaction types.

The DBID value used by a Snoop Completer in response to a Stash snoop that includes a Data Pull must be unique with respect to:

- The DBID values in other Snoop responses to Stash snoops that use Data Pull.
- The TxnID of any outstanding request from that Snoop Completer.

The Completer is not required to utilize the DBID field, and is permitted to set it to any value in:

- WriteNoSnpZero and WriteUniqueZero transactions.
- Read transactions without CompAck.
- Dataless transactions without CompAck.
- Snoop response to a Stash snoop that does not include a Data Pull.
- Snoop response to a Non-stash snoop.

————— Note —————

The advantage of using the DBID assigned by the Completer, instead of the TxnID assigned by the Requester, is that the Completer can use the DBID to index into its request structure instead of performing a lookup using TxnID and SrcID to determine which transaction write data or completion acknowledgment is associated with which request.

If a Completer is using the same DBID value for different Requesters, which it must do if its operation requires more than 1024 DBID responses to be active at the same time, it must use SrcID with DBID to determine which request should be associated with a write data or response message.

The DBIDResp response is also used to provide certain ordering guarantees relating to the transaction. See [Transaction ordering on page 2-125](#).

2.4.4 Return Transaction Identifier, ReturnTxnID

A transaction request from Home to Subordinate also includes a ReturnTxnID field to convey the value of TxnID in the data response and the DBIDResp response from the Subordinate. Its value, when applicable, must be either:

- The TxnID generated by Home, when the ReturnNID is the node ID of the Home.
- The TxnID of the original Requester, when the ReturnNID is the node ID of the original Requester.

ReturnTxnID is only applicable in a ReadNoSnP, ReadNoSnPSep, WriteNoSnP, Combined Write, and Atomic requests from Home to Subordinate. The field is inapplicable and must be set to zero in all other requests from Home to Subordinate.

ReturnTxnID is inapplicable and must be set to zero in all requests from Requester to Home and Requester to Subordinate.

The following are the expected and permitted values for ReturnTxnID in requests from the Home Node to the Subordinate Node.

In ReadNoSnP and ReadNoSnPSep:

- Expected value is the original Requester TxnID but permitted to be the Home TxnID.
- Used as the TxnID in the CompData and DataSepResp responses.

In Atomic with TagOp *Invalid* or *Match*:

- For AtomicStore, the ReturnTxnID can take any value, and the value is not used in any response.
- For Non-store Atomics, the ReturnTxnID must be the Home TxnID. The value is used as the TxnID in the CompData response.

In WriteNoSnP with any TagOp value:

- When DoDWT = 0, ReturnTxnID can take any value, and the value is not used in any response.
- When DoDWT = 1, ReturnTxnID value is expected to be the original Requester TxnID but is permitted to be the Home TxnID. Used as the TxnID in the DBIDResp response.

In Combined Write:

- When DoDWT = 0, ReturnTxnID can take any value, and the value is not used in any response.
- When DoDWT = 1, ReturnTxnID value is expected to be the original Requester TxnID but is permitted to be the Home TxnID. Used as the TxnID in the DBIDResp response.

2.4.5 Forward Transaction Identifier, FwdTxnID

A Snoop request from Home to RN-F also includes a FwdTxnID field to convey the value of TxnID in the Data response from the Snoopee. Its value must be the TxnID of the original Request.

The FwdTxnID field is only applicable in:

- SnpSharedFwd
- SnpCleanFwd
- SnpOnceFwd
- SnpNotSharedDirtyFwd
- SnpUniqueFwd
- SnpPreferUniqueFwd

It is inapplicable and must be set to zero in all other snoops.

2.4.6 Data Identifier, DataID, and Critical Chunk Identifier, CCID

These fields identify the individual data packets within a transaction.

See [Data packetization on page 2-144](#) and [Critical Chunk Identifier on page 2-148](#).

2.4.7 Logical Processor Identifier, LPID

This field is used when a single Requester contains more than one logically separate processing agent. The SrcID is used with LPID to uniquely identify the logical processor that generated the request.

The LPID must be set to the correct value for the following transactions:

- For any Non-snoopable Non-cacheable or Device access:
 - ReadNoSnp
 - WriteNoSnp
- For Exclusive accesses, that can be one of the following transaction types:
 - ReadClean
 - ReadShared
 - ReadNotSharedDirty
 - ReadPreferUnique
 - MakeReadUnique
 - CleanUnique
 - ReadNoSnp
 - WriteNoSnp

See [Chapter 6 Exclusive accesses](#) for further details.

For other transactions, the LPID value is permitted, but not required, to indicate the original logical processor that caused a transaction to be issued.

In requests, when applicable, the same bits in the packet are used for TagGroupID, PGroupID, and StashGroupID.

2.4.8 Stash Logical Processor Identifier, StashLPID

The StashLPID field can be used to specify a particular LP within the Request Node specified by StashNID, when the corresponding StashLPIDValid bit is asserted. See [Stash Logical Processor Identifier; StashLPID on page 13-427](#).

See [Supporting REQ packet fields on page 7-310](#) for the permitted combinations of StashLPIDValid and StashNIDValid.

2.4.9 Stash Node Identifier, StashNID

The StashNID field provides Request Node that is the target of the Stash transaction when the corresponding StashNIDValid bit is asserted. See [Stash Node Identifier; StashNID on page 13-426](#).

2.4.10 Return Node Identifier, ReturnNID

A transaction request from Home to Subordinate includes a ReturnNID that is used to determine the TgtID for the following responses from the Subordinate Node:

- Data response
- DBIDResp response
- Persist response
- TagMatch response

Its value must be either the node ID of Home or the node ID of the original Requester.

ReturnNID is only applicable in a ReadNoSnP, ReadNoSnPSeq, CleanSharedPersistSeq, WriteNoSnP, Combined Write, and Atomic requests from Home to Subordinate. The field is inapplicable and must be set to zero in all other requests from Home to Subordinate.

ReturnNID is inapplicable and must be set to zero in all requests from Requester to Home and Requester to Subordinate.

The following are the expected and permitted values for the ReturnNID in requests from the Home Node to the Subordinate Node.

In ReadNoSnP, ReadNoSnPSeq, and CleanSharedPersistSeq:

- Expected value is the original Requester Node ID but is permitted to be the Home Node ID.
- Used as the TgtID in CompData, DataSepResp and Persist responses.

In Atomic with TagOp *Invalid*:

- For AtomicStore, ReturnNID can take any value and the value is not used in any responses.
- For Non-store Atomics, the ReturnNID must be the Home Node ID. The value is used as the TgtID in CompData.

In Atomic with TagOp *Match*:

- ReturnNID must be the Home Node ID.
- The value is used as the TgtID in CompData and TagMatch responses.

In WriteNoSnP with TagOp not *Match*:

- When DoDWT = 0, the ReturnNID can take any value, and the value is not used in any responses.
- When DoDWT = 1, the ReturnNID value is expected to be the original Requester Node ID but is permitted to be the Home Node ID. Used as the TgtID in the DBIDResp response.

In WriteNoSnP with TagOp *Match*:

- Irrespective of the value of DoDWT, the ReturnNID value is expected to be the original Requester Node ID but is permitted to be the Home Node ID.
- When DoDWT = 0, the value is used as the TgtID in the TagMatch response only.
- When DoDWT = 1, the value is used as the TgtID in the DBIDResp and TagMatch responses.

In Non-PCMO Combined Write:

- When DoDWT = 0, the ReturnNID can take any value, and the value is not used in any responses.
- When DoDWT = 1, the ReturnNID value is expected to be the original Requester Node ID but is permitted to be the Home Node ID. Used as the TgtID in the DBIDResp response.

In WriteNoSnPFullClnShPer and WriteNoSnPtlClnShPer:

- Irrespective of the value of DoDWT, the ReturnNID value is expected to be the original Requester Node ID but is permitted to be the Home Node ID.
- When DoDWT = 0, the value is used as the TgtID in the Persist response only.
- When DoDWT = 1, the value is used as the TgtID in the DBIDResp and Persist responses.

2.4.11 Home Node Identifier, HomeNID

CompData includes the HomeNID field that is used by the Requester to identify the target of the CompAck that it might need to send in response to CompData. HomeNID is applicable in CompData and DataSepResp and is inapplicable and must be set to zero for all other Data messages.

————— Note —————

There is no functional requirement for the HomeNID and DBID fields in the DataSepResp response because the values that are provided in the RespSepData response are identical and can always be used. However, it is required that these values are included to help with debugging and protocol checking.

2.4.12 Forward Node Identifier, FwdNID

A Snoop request from Home to RN-F includes a FwdNID that is used to determine the TgtID for the Data response from the Snoopee. Its value must be the Node ID of the original Requester.

The FwdNID field is only applicable in:

- SnpSharedFwd
- SnpCleanFwd
- SnpOnceFwd
- SnpNotSharedDirtyFwd
- SnpUniqueFwd
- SnpPreferUniqueFwd

It is inapplicable and must be set to zero in all other snoops, except range-based TLBI DVM operations. For range-based TLBI operations, the bits in the field are used for DVM payload.

2.4.13 Persistence Group Identifier, PGroupID

A CleanSharedPersistSep and *Combined Write with Persistent CMO* (PCMO) request includes a PGroupID to identify the Persistence Group that the request belongs to. If a Requester has persistent CMO requests from different functional agents that it would like to identify for performant persistent CMO handling, it can assign a different PGroupID value to each group of Persist requests. Use of this 8-bit field is applicable in CleanSharedPersistSep and Combined Write with PCMO transactions. It is also applicable in Persist and CompPersist responses. It is inapplicable and must be set to zero in all other requests and responses. See [Persistence Group Identifier, PGroupID on page 13-426](#):

- PGroupID must be sent in the CleanSharedPersistSep request and a Combined Write request that includes a PCMO.
- The PGroupID value returned in the Persist response can be used by a Requester to separately track completions of Persist responses from each group.
- It is expected that a Requester that does not support multiple persistence groups sets the PGroupID value to zero.
- A Requester that is making use of PGroupID for passing a barrier typically will not reuse a PGroupID value until all the earlier sent CleanSharedPersistSep requests from that group have received Persist responses.
- The Completer is required to reflect back PGroupID in the Persist and CompPersist responses, and the responses of Combined Write requests that include a PCMO.
- The PGroupID field in the Comp and CompCMO response from both the Home and Subordinate is inapplicable and must be set to zero.

2.4.14 Stash Group Identifier, StashGroupID

To identify the Stash group that the request belongs to, a StashOnceSep request includes a StashGroupID. The same StashGroupID value from the request is then used by a StashDone response later on in the transaction flow. If a Requester has StashOnceSep requests from different functional agents that it would like to identify for performant stash handling, it can assign a different StashGroupID value to each group of Stash requests.

Use of this 8-bit field is applicable in the StashOnceSep request and StashDone response. It is inapplicable and must be set to zero in all other requests and responses.

- StashGroupID must be sent in the StashOnceSep request.
- The StashGroupID value returned in the StashDone response can be used by a Requester to separately track completions of Stash transactions from each group.
- It is expected that a Requester that does not support multiple stash groups sets the StashGroupID value to zero.

- The Completer is required to reflect back StashGroupID in the StashDone response.

See *Stash Group Identifier, StashGroupID* on page 13-427.

2.4.15 Tag Group Identifier, TagGroupID

To identify the Tag group that the request belongs to, a Write request where TagOp is set to *Match* includes a TagGroupID. The same TagGroupID value from the request is then used by a TagMatch response later on in the transaction flow to notify the Requester if the TagMatch operation passed or failed.

Use of this 8-bit field is applicable in Write requests where TagOp is set to *Match*, and in a TagMatch response. It is inapplicable and must be set to zero in all other requests and responses.

- TagGroupID must be sent in a Write request where TagOp is set to Match.
- The precise contents of TagGroupID are implementation defined. Typically, TagGroupID is expected to contain an Exception Level, TTBR value, and PE identifier.

See *Tag Group Identifier, TagGroupID* on page 13-443.

2.5 Transaction identifier field flows

This section shows the transaction identifier field flows for the different transaction types:

- [Read transactions on page 2-101](#)
- [Dataless transactions on page 2-109](#)
- [Write transactions on page 2-111](#)
- [DVMOp transaction on page 2-119](#)
- [Transaction requests with Retry on page 2-119](#)
- [Protocol Credit Return transaction on page 2-120](#)

In the associated figures:

- The fields included in each packet are:
 - For a Request packet: TgtID, SrcID, TxnID, StashNID, StashLPID, ReturnNID, ReturnTxnID, PGroupID, StashGroupID, and TagGroupID.
 - For a Response packet: TgtID, SrcID, TxnID, DBID, PGroupID, StashGroupID, and TagGroupID.
 - For a Data packet: TgtID, SrcID, TxnID, HomeNID, and DBID.
 - For a Snoop packet: SrcNID, TxnID, FwdNID, FwdTxnID, and StashLPID.
- All fields with the same color are the same value.
- The curved loop-back arrows show how the Requester and Completer use fields from earlier packets to generate fields for subsequent packets.
- A box containing an asterisk [*] indicates when a field is first generated, that is, it indicates the agent that determines the original value of the field.
- A field enclosed in parentheses indicates that the value is effectively a fixed value. Typically this is the case for the SrcID field when a packet is sent, and the TgtID field when a packet arrives at its destination.
- A field that is crossed-out indicates that the field is not valid.
- It is permitted for the TgtID of the original transaction to be remapped by the interconnect to a new value. This is shown by a box containing the letter R. This is explained in more detail in [Chapter 3 Network Layer](#).

———— Note —————

An identifier field, in every packet sent, belongs to one of the following categories:

- New value. An asterisk indicates that a new value is generated.
- Generated from an earlier packet. A loop back arrow indicates the source.
- Fixed value. The value is enclosed in brackets.
- Not valid. The field is crossed-out.

In the following examples, any transaction identifiers that are not relevant for the example are sometimes omitted for clarity.

2.5.1 Read transactions

This section shows identifier field flows in Read transactions with and without Direct Data Transfer:

- [ID value transfer with DMT](#)
- [ID value transfer with DMT and separate Comp and Data on page 2-103](#)
- [ID value transfer with DCT on page 2-105](#)
- [ID value transfer without Direct Data Transfer on page 2-107](#)

ID value transfer with DMT

Figure 2-23 shows how the Target and Transaction ID values in the DMT transaction messages are derived. For example, the value of SrcID in the ReadNoSnp request from the interconnect is assigned by the interconnect. Whereas the ReturnNID, used as TgtID in the Data response, is set to the value of SrcID of the received Read request.

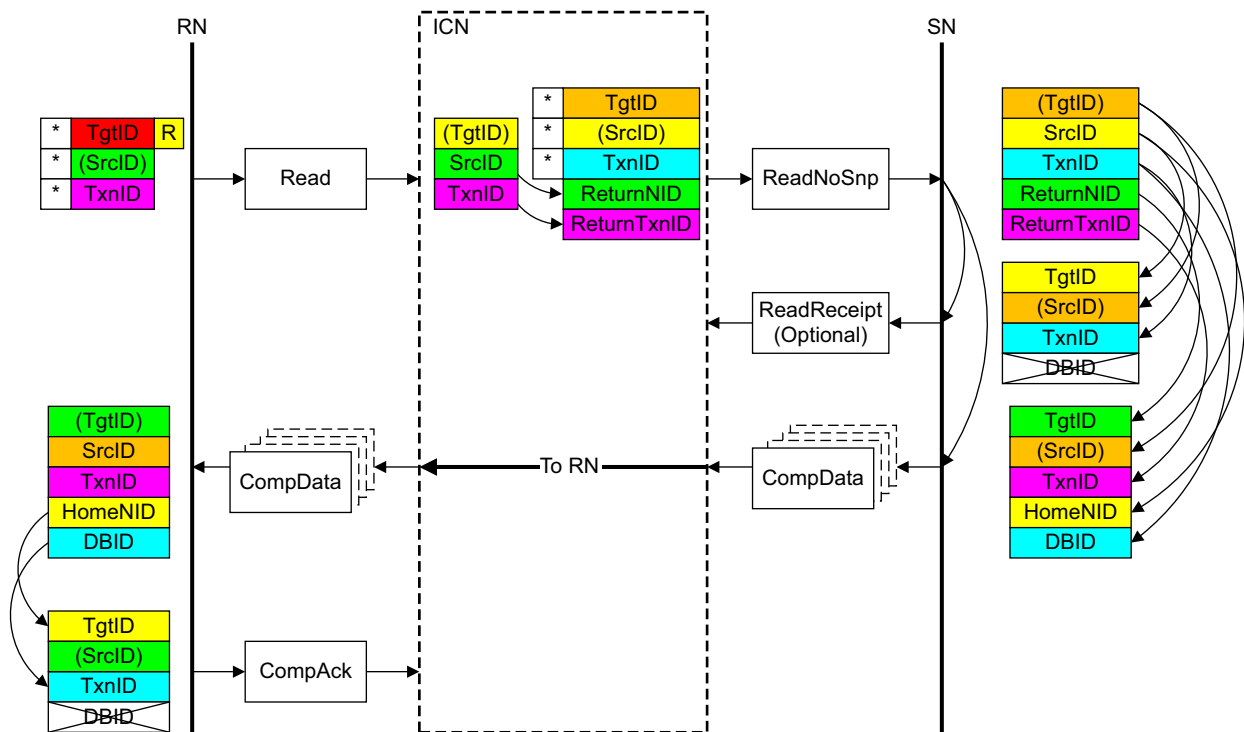

Figure 2-23 ID value transfer in a DMT transaction

The required steps in the flow that Figure 2-23 shows are:

1. The Requester starts the transaction by sending a Request packet.

The identifier fields of the request are generated as follows:

- The TgtID is determined by the destination of the Request.

Note

The TgtID field can be remapped to a different value by the interconnect.

- The SrcID is a fixed value for the Requester.
- The Requester generates a TxnID field that is unique for that Requester.

2. The recipient Home Node in the interconnect generates a Request to the Subordinate Node.
The identifier fields of the request are generated as follows:
 - The TgtID is set to the value required for the Subordinate.
 - The SrcID is a fixed value for the Home.
 - The TxnID is a unique value generated by the Home.
 - The ReturnNID is set to the same value as the SrcID of the original request.
 - The ReturnTxnID is set to the same value as the TxnID of the original request.
3. If the request to the Subordinate requires a ReadReceipt, the Subordinate provides the read receipt.
The identifier fields of the ReadReceipt response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Subordinate. This also matches the TgtID received.
 - The TxnID is set to the same value as the TxnID of the request.
 - The DBID field is not valid.
4. The Subordinate provides the read data.
The identifier fields of the Read data response are generated as follows:
 - The TgtID is set to the same value as the ReturnNID of the request.
 - The SrcID is a fixed value for the Subordinate. This also matches the TgtID received.
 - The TxnID is set to the same value as the ReturnTxnID of the request.
 - The HomeNID is set to the same value as the SrcID of the request.
 - The DBID is set to the same value as the TxnID of the request.
5. The Requester receives the read data and sends a completion acknowledge, CompAck, response.
The identifier fields of the CompAck are generated as follows:
 - The TgtID is set to the same value as the HomeNID of the read data.
 - The SrcID is a fixed value for the Requester. This also matches the TgtID that was received.
 - The TxnID is set to the same value as the DBID of the read data.
 - The DBID field is not valid.

The CompAck response from Requester to Home is not required for all requests.

If the original request requires a ReadReceipt, the following additional step is included:

- The Home receives the Request packet and provides the read receipt.
The identifier fields of the ReadReceipt response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Completer. This also matches the TgtID received.
 - The TxnID is set to the same value as the TxnID of the request.
 - The DBID field is not valid.

[Transaction identifier fields on page 2-93](#) details when the TxnID value and DBID value can be reused.

ID value transfer with DMT and separate Comp and Data

Figure 2-24 shows how the identifier field values are derived in DMT transaction messages that use separate Comp and Data.

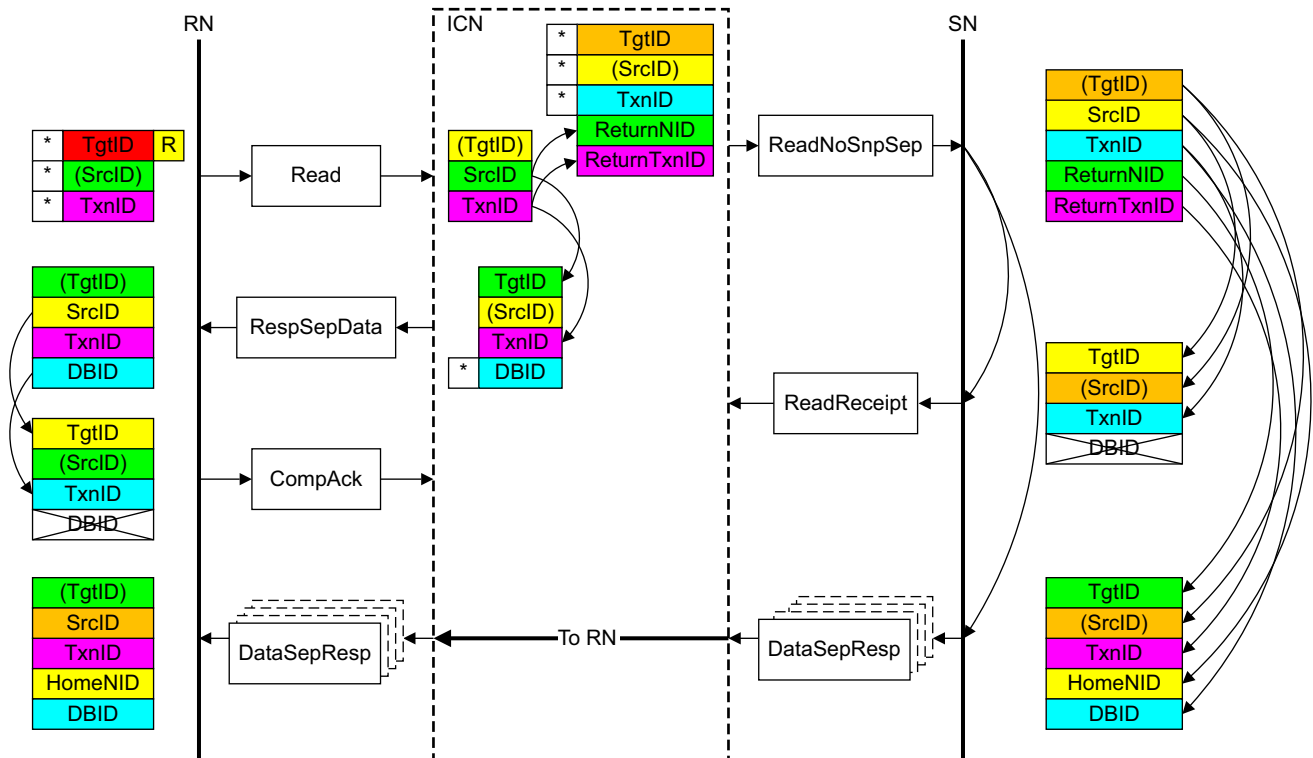

Figure 2-24 ID value transfer in a DMT transaction with separate Comp and Data

The required steps in the flow that Figure 2-24 shows are:

- The Requester starts the transaction by sending a Request packet.
The identifier fields of the request are generated as follows:
 - The TgtID is determined by the destination of the Request.

————— Note —————

The TgtID field can be remapped to a different value by the interconnect.

 - The SrcID is a fixed value for the Requester.
 - The Requester generates a TxnID field that is unique for that Requester.
- The recipient Home Node in the interconnect generates a request to the Subordinate Node.
The identifier fields of the request are generated as follows:
 - The TgtID is set to the value required for the Subordinate.
 - The SrcID is a fixed value for the Home.
 - The TxnID is a unique value generated by the Home.
 - The ReturnNID is set to the same value as the SrcID of the original request.
 - The ReturnTxnID is set to the same value as the TxnID of the original request.

3. The recipient Home Node in the interconnect provides the separate Read response.
The identifier fields of the read response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Home.
 - The TxnID is set to the same value as the TxnID of the original request.
 - The DBID value is a unique value generated by the Home and is the same value as the TxnID in the request to the Subordinate.
4. The Requester receives the Read response and sends a completion acknowledge, CompAck, response.
The identifier fields of the CompAck are generated as follows:
 - The TgtID is set to the same value as the SrcID of the read response.
 - The SrcID is a fixed value for the Requester.
 - The TxnID is set to the unique DBID value generated by the Home.
 - The DBID value is not valid.
5. The request to the Subordinate requires a ReadReceipt. The Subordinate provides the read receipt.
The identifier fields of the ReadReceipt response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Subordinate. This also matches the TgtID received.
 - The TxnID is set to the same value as the TxnID of the request.
6. The Subordinate provides the separate read data.
The identifier fields of the read data are generated as follows:
 - The TgtID is set to the same value as the ReturnNID of the request.
 - The SrcID is a fixed value for the Subordinate. This also matches the TgtID received.
 - The TxnID is set to the same value as the ReturnTxnID of the request.
 - The HomeNID is set to the same value as the SrcID of the request.
 - The DBID is set to the same value as the TxnID of the request.

ID value transfer with DCT

Figure 2-25 shows how the identifier field values are derived in DCT transaction messages. In this example, the data is forwarded to a Request Node and a Snoop response is sent to HN-F with or without data.

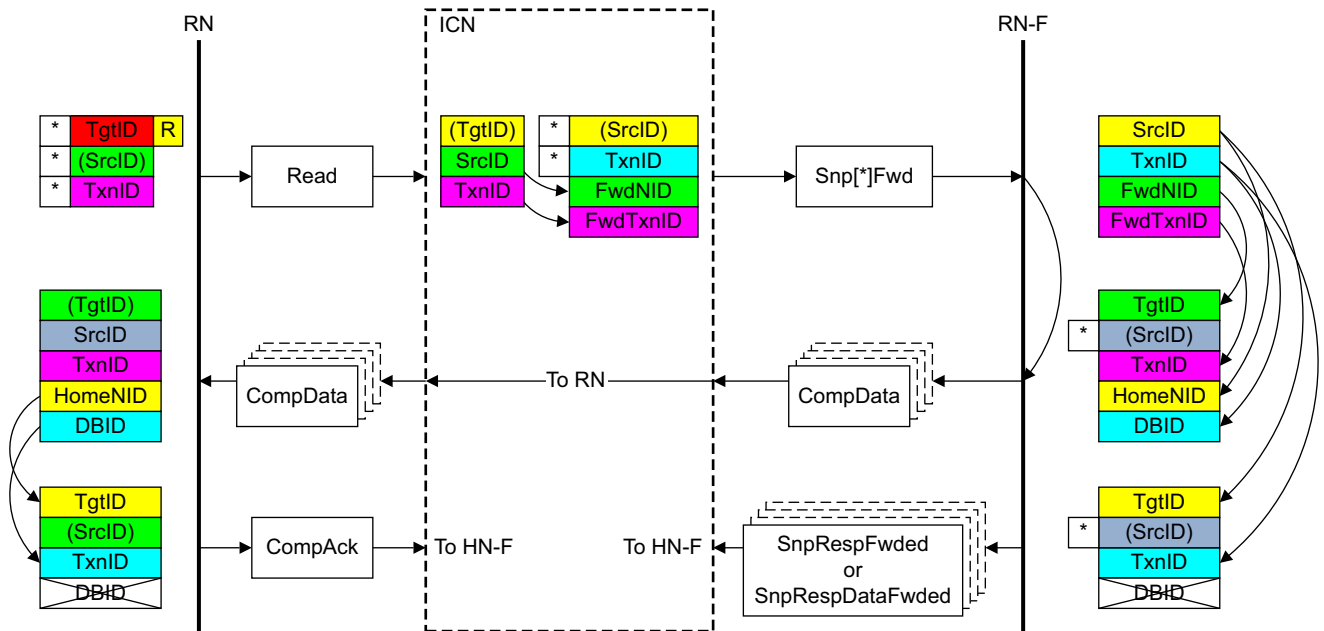

Figure 2-25 ID value transfer in a DCT transaction

The required steps in the flow that Figure 2-25 shows are:

- The Requester starts the transaction by sending a Request packet.
The identifier fields of the request are generated as follows:
 - The TgtID is determined by the destination of the Request.

————— Note —————
The TgtID field can be remapped to a different value by the interconnect.

 - The SrcID is a fixed value for the Requester.
 - The Requester generates a TxnID field that is unique for that Requester.
- The recipient Home Node in the interconnect generates a Forwarding snoop to the RN-F node.
The identifier fields of the snoop are generated as follows:
 - The SrcID is a fixed value for the Home.
 - The TxnID is a unique value generated by the Home.
 - The FwdNID is set to the same value as the SrcID of the original request.
 - The FwdTxnID is set to the same value as the TxnID of the original request.
- The RN-F provides the read data.
The identifier fields of the Read data response are generated as follows:
 - The TgtID is set to the same value as the FwdNID of the snoop.
 - The SrcID is a fixed value for the RN-F.
 - The TxnID is set to the same value as the FwdTxnID of the snoop.
 - The HomeNID is set to the same value as the SrcID of the snoop.
 - The DBID is set to the same value as the TxnID of the snoop.

4. The RN-F also provides a response to Home, either with or without read data.
The identifier fields of the response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the snoop.
 - The SrcID is a fixed value for the RN-F.
 - The TxnID is set to the same value as the TxnID of the snoop.
 - The DBID field is not valid.
5. The Requester receives the read data and sends a completion acknowledge, CompAck, response.
The identifier fields of the CompAck are generated as follows:
 - The TgtID is set to the same value as the HomeNID of the read data.
 - The SrcID is a fixed value for the Requester. This also matches the TgtID that was received.
 - The TxnID is set to the same value as the DBID of the read data.
 - The DBID field is not valid.

Note

An optional ReadReceipt from the interconnect to Requester can also be included.

ID value transfer without Direct Data Transfer

This section gives an example of a Read identifier field flow without DMT or DCT and describes the use of the TxnID and DBID fields for Read transactions.

The Requester and Completer in this example are a Request Node and an HN-F respectively.

The identifier field flow includes an optional ReadReceipt response from the Completer, and an optional CompAck response from the Requester.

For Read transactions that include a CompAck response, the DBID is used by the Completer to associate the CompAck with the original transaction.

A Read transaction that does not include a CompAck response does not require a valid DBID field in the data response.

Figure 2-26 shows the ID value transfer.

Figure 2-26 ID value transfer in a Read request with ReadReceipt and CompAck

The required steps in the flow that Figure 2-26 shows are:

1. The Requester starts the transaction by sending a Request packet.

The identifier fields of the request are generated as follows:

- The TgtID is determined by the destination of the Request.

Note

The TgtID field can be re-mapped to a different value by the interconnect.

- The SrcID is a fixed value for the Requester.
- The Requester generates a TxnID field that is unique for that Requester.

2. If the transaction includes a ReadReceipt, the Completer receives the Request packet and provides the read receipt.

The identifier fields of the ReadReceipt response are generated as follows:

- The TgtID is set to the same value as the SrcID of the request.
- The SrcID is a fixed value for the Completer. This also matches the TgtID received.
- The TxnID is set to the same value as the TxnID of the request.
- The DBID field is not valid.

3. The Completer receives the Request packet and provides the read data.

The identifier fields of the read data response are generated as follows:

- The TgtID is set to the same value as the SrcID of the request.
- The SrcID is a fixed value for the Completer. This also matches the TgtID received.
- The TxnID is set to the same value as the TxnID of the request.
- The HomeNID is a fixed value for the Completer. This also matches the TgtID received.
- The Completer generates a unique DBID value if ExpCompAck in the request is asserted.

4. The Requester receives the read data and sends a completion acknowledge, CompAck, response.

The identifier fields of the CompAck are generated as follows:

- The TgtID is set to the same value as the HomeNID of the read data.
- The SrcID is a fixed value for the Requester. This also matches the TgtID that was received.
- The TxnID is set to the same value as the DBID of the read data.
- The DBID field is not valid.

2.5.2 Dataless transactions

For Dataless transactions, with the exception of CleanSharedPersistSep and StashOnceSep, the use of identifier fields is similar to *ID value transfer without Direct Data Transfer* on page 2-107. The only difference is that the response from the Completer to the Requester is sent as a single packet on the CRSP channel instead of multiple packets on the RDAT channel.

For StashOnceSep transactions, the StashGroupID value is sent in the request from the Request Node to the interconnect and the value is returned in the StashDone and CompStashDone responses. The TxnID value in the StashDone response is inapplicable and must be set to zero.

The description of ID value transfer in a CleanSharedPersistSep transaction follows.

ID value transfer in a CleanSharedPersistSep transaction

Figure 2-27 shows how the identifier field values are derived in CleanSharedPersistSep transaction messages that use separate Comp and Persist responses. In Figure 2-27, PCMOsep represents CleanSharedPersistSep.

Figure 2-27 ID value transfer in a CleanSharedPersistSep transaction

The required steps in the flow that Figure 2-27 shows are:

- The Requester starts the transaction by sending a Request packet. The identifier fields of the Request are generated as follows:
 - The TgtID is determined by the destination of the Request.

Note

The TgtID field can be remapped to a different value by the interconnect.

 - The SrcID is a fixed value for the Requester.
 - The Requester generates a TxnID value that is unique for that Requester. The TxnID value can be reused by the Requester after receiving the Comp response.
 - The Requester generates a new PGroupID value, or reuses a PGroupID value currently in use.

2. The recipient Home Node in the interconnect generates a request to the Subordinate.
The identifier fields of the request to the Subordinate Node are generated as follows:
 - The TgtID is set to the value required for the Subordinate.
 - The SrcID is a fixed value for the Home.
 - The TxnID is a unique value generated by the Home.
The TxnID value can be reused by the Home after receiving the Comp response.
 - The ReturnNID is set to the same value as the SrcID of the original request.
 - The ReturnTxnID is inapplicable and must be set to zero.
 - The PGroupID is set to the same value as the PGroupID of the original request.
3. The recipient Home Node in the interconnect sends a Comp response to the Requester.
The identifier fields of the Comp response to the Requester are generated as follows:
 - The TgtID is set to the same value as the SrcID of the original request.
 - The SrcID is a fixed value for the Home.
 - The TxnID is set to the same value as the TxnID of the original request.
4. The recipient Home Node can optionally send a Persist response to the Requester.
The identifier fields of the optional Persist response from the Home Node to the Requester, not shown in [Figure 2-27 on page 2-109](#), are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Home Node.
 - The TxnID is inapplicable and must be set to zero.
 - The PGroupID is set to the same value as the PGroupID of the request.

The recipient Home Node can optionally send a combined CompPersist response to the Requester, instead of separate Comp and Persist responses.

The identifier fields in the CompPersist response are generated as follows:

 - The TgtID is set to the same value as the SrcID of the original request.
 - The SrcID is a fixed value for the Home.
 - The TxnID is set to the same value as the TxnID of the original request.
 - The PGroupID is set to the same value as the PGroupID of the original request.
5. The Subordinate Node generates a Comp to the Home Node.
The identifier fields of the Comp response from the Subordinate Node are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Subordinate.
 - The TxnID is set to the same value as the TxnID of the request.
6. The Subordinate Node also generates a Persist response to either to the Requester or the Home.
The identifier fields of the Persist response from the Subordinate Node are generated as follows:
 - The TgtID is set to the same value as the ReturnNID of the request.
 - The SrcID is a fixed value for the Subordinate.
 - The TxnID is inapplicable and must be set to zero.
 - The PGroupID is set to the same value as the PGroupID of the request.
7. The Subordinate Node can optionally send a combined CompPersist response to the Home Node, instead of separate Comp and Persist responses if the ReturnNID and SrcID of the request are the same value.
The identifier fields of the CompPersist response from the Subordinate are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Subordinate.
 - The TxnID is set to the same value as the TxnID of the request.
 - The PGroupID is set to the same value as the PGroupID of the request.

2.5.3 Write transactions

This section describes the use of the TxnID and DBID fields for Write transactions:

- [CopyBack transaction](#)
- [WriteNoSnp transaction on page 2-113](#)
- [WriteUnique transaction on page 2-115](#)
- [StashOnce or StashOnceSep transaction on page 2-117](#)

CopyBack transaction

This section describes the use of the identifier fields for a CopyBack transaction.

Figure 2-28 shows the identifier value transfer.

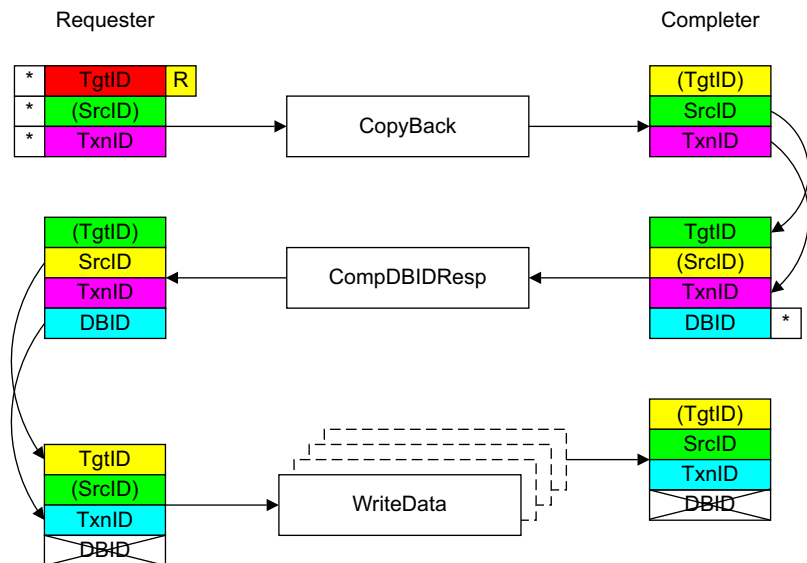

Figure 2-28 ID value transfer in a CopyBack

The required steps in the flow that Figure 2-28 shows are:

1. The Requester starts the transaction by sending a Request packet. The identifier fields of the request are generated as follows:
 - The TgtID is determined by the destination of the Request.

———— Note ————

The TgtID field can be remapped to a different value by the interconnect.

 - The SrcID is a fixed value for the Requester.
 - The Requester generates a unique TxnID field.
2. The Completer receives the Request packet and generates a CompDBIDResp response. The identifier fields of the response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Completer. This also matches the TgtID received.
 - The TxnID is set to the same value as the TxnID of the request.
 - The Completer generates a unique DBID value.

3. The Requester receives the CompDBIDResp response and sends the write data. The identifier fields of the write data are generated as follows:
 - The TgtID is set to the same value as the SrcID of the CompDBIDResp response. This can be different from the original TgtID of the request if the value was remapped by the interconnect.
 - The SrcID is a fixed value for the Requester.
 - The TxnID is set to the same value as the DBID value provided in the CompDBIDResp response.
 - The DBID field in the write data is not used.
 - The TgtID, SrcID, and TxnID fields must be the same for all write data packets.

After receiving the CompDBIDResp response, the Requester can reuse the same TxnID value used in the request packet for another transaction.

4. The Completer receives the write data and uses the TxnID field, which now contains the DBID value that the Completer generated. This helps to determine which transaction to associate the write data.

After receiving all write data packets, the Completer can reuse the same DBID value for another transaction.

WriteNoSnp transaction

This section describes the use of the identifier fields for a WriteNoSnp transaction.

Figure 2-29 does not show the Memory Tagging supported TagGroupID flow. For TagGroupID transfer details see *Write transactions on page 12-386 in Chapter 12 Memory Tagging*.

Figure 2-29 shows the identifier value transfer for separate Comp and DBIDResp. The Completer can opportunistically combine the Comp and DBIDResp into a single CompDBIDResp response. The Requester can opportunistically combine NCBWrData with CompAck.

Figure 2-29 ID value transfer in a WriteNoSnp

The uses of the identifier fields are the same as for a transaction with a combined response with the additional requirements that:

- The identifier fields used for the separate DBIDResp and Comp responses must be identical.
- The TxnID value must only be reused by a Requester when both the DBIDResp and Comp responses have been received.

The required steps in the flow that [Figure 2-29 on page 2-113](#) shows are:

1. The Requester starts the transaction by sending a Request packet. The identifier fields of the request are generated as follows:
 - The TgtID is determined by the destination of the Request.

Note

The TgtID field can be remapped to a different value by the interconnect.

 - The SrcID is a fixed value for the Requester.
 - The Requester generates a unique TxnID field.
2. The Completer receives the Request packet and generates a DBIDResp response. The identifier fields of the response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Completer. This also matches the TgtID received.
 - The TxnID is set to the same value as the TxnID of the request.
 - The Completer generates a unique DBID value.
3. The Requester receives the DBIDResp response and sends the write data. The identifier fields of the write data are generated as follows:
 - The TgtID is set to the same value as the SrcID of the DBIDResp response. This can be different from the original TgtID of the request if the value was remapped by the interconnect.
 - The SrcID is a fixed value for the Requester.
 - The TxnID is set to the same value as the DBID value provided in the DBIDResp response.
 - The DBID field in the write data is not used.
 - The TgtID, SrcID, and TxnID fields must be the same for all write data packets.
4. The Completer receives the write data and uses the TxnID field, which now contains the DBID value that the Completer generated, to determine which transaction the write data is associated with.
5. The Completer generates a Comp response when it has completed the transaction.

The identifier fields of the Comp response must be the same as the DBIDResp response and are generated as follows:

 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Completer. This also matches the TgtID received.
 - The TxnID is set to the same value as the TxnID of the request.
 - The Completer uses the same DBID value as is used in the DBIDResp response.
6. The Requester sends a CompAck message, if the transaction requires it, after receiving DBIDResp or Comp. The identifier fields of the CompAck are generated as follows:
 - The TgtID is set to the same value as the SrcID of the DBIDResp or Comp response.
 - The SrcID is a fixed value for the Requester. This also matches the TgtID that was received.
 - The TxnID is set to the same value as the DBID of the DBIDResp or Comp response.
 - The DBID field is not valid.

After receiving both the Comp and DBIDResp response, the Requester can reuse the same TxnID value for another transaction.

After receiving all the write data packets, the Completer can reuse the same DBID value for another transaction.

Note

There is no ordering requirement between the separate DBIDResp and Comp responses. It is required that the values used are identical when the two messages originate from the same source.

WriteUnique transaction

This section describes the use of the identifier fields for a WriteUnique transaction.

Figure 2-30 does not show the Memory Tagging supported TagGroupID flow, For TagGroupID transfer details see *Write transactions on page 12-386 in Chapter 12 Memory Tagging*.

Under certain circumstances, the WriteUnique transaction can also include a CompAck response from the Requester to the Completer. In this case, the additional rules for the use of the identifier fields are:

- The TgtID, SrcID, and TxnID identifier fields of the CompAck response from the Requester to the Completer must be the same as the fields used for the write data, that is:
 - The TgtID is set to the same value as the SrcID of the CompDBIDResp response. If separate Comp and DBIDResp responses are given, the TgtID is set to the same value as the SrcID of either the Comp or DBIDResp response because the SrcID value in both must be identical. However, this can be different from the original TgtID of the request if the value has been remapped by the interconnect.
 - The SrcID is a fixed value for the Requester.
 - The TxnID is set to the same value as the DBID value provided in the CompDBIDResp response. If separate Comp and DBIDResp responses are given, the TxnID is set to the same value as the DBID of either the Comp or DBIDResp response because the DBID value in both must be identical.
 - The DBID field in the WriteData and in the CompAck is not used.
 - If a combined WriteData and CompAck response is sent, then the TgtID is set to the same value as the SrcID in the Comp, DBIDResp, or CompDBIDResp, and the TxnID in the combined response is set to the same value as the DBID in Comp, DBIDResp, or CompDBIDResp.
- The Completer must receive all items of write data and the CompAck response before reusing the same DBID value for another transaction.

Figure 2-30 shows the identifier value transfer with a combined CompDBIDResp response.

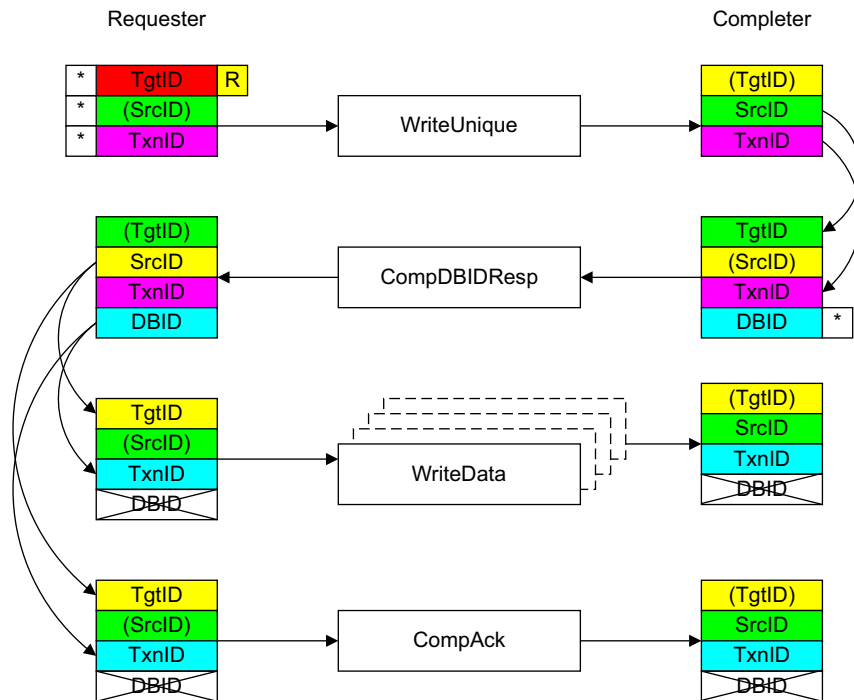

Figure 2-30 ID value transfer with a combined CompDBIDResp response

Figure 2-31 on page 2-116 shows the identifier value transfer with a combined WriteData and CompAck response.

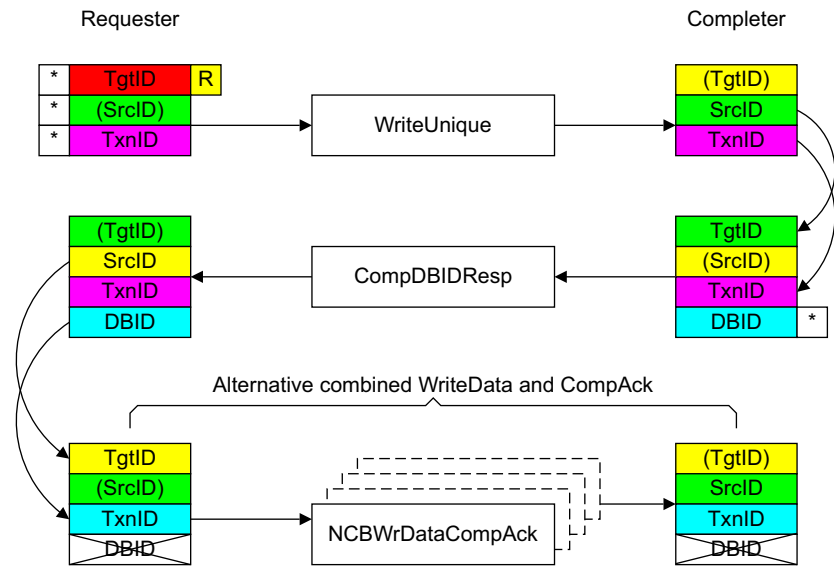

Figure 2-31 ID value transfer with a combined WriteData and CompAck response

StashOnce or StashOnceSep transaction

This section describes the use of the identifier fields for a StashOnce or StashOnceSep transaction with DataPull.

Figure 2-32 shows the identifier value transfer.

Figure 2-32 ID value transfer in a Stash transaction

The required steps in the flow that [Figure 2-32](#) shows are:

1. The Requester starts the transaction by sending a Stash request packet.
The identifier fields of the request are generated as follows:
 - The TgtID is determined by the destination of the Request.

Note

The TgtID field can be remapped to a different value by the interconnect.
 - The SrcID is a fixed value for the Requester.
 - The Requester generates a TxnID field that is unique for that Requester.
 - The Requester includes the StashNID field to indicate to which RN-F to send the Stash.
 - The Requester includes the StashLPID field to indicate the logical processor within the RN-F.

2. The Home Node in the interconnect receives the Stash request packet and sends the Comp response to the Request Node.

The identifier fields of the Comp response are generated as follows:

- The TgtID is set to the same value as the SrcID of the request.
- The TxnID is set to the same value as the TxnID of the request.

3. The Home Node in the interconnect, for the StashOnceSep request, sends the StashDone response to the Request Node.

The identifier fields of the StashDone response are generated as follows:

- The TgtID is set to the same value as the SrcID of the request.
- The TxnID is not valid.
- StashGroupID is set to the same value as the StashGroupID of the request.

Alternatively for the StashOnceSep request, the Home Node in the interconnect sends the combined CompStashDone response instead of separate Comp and StashDone responses to the Request Node.

The identifier fields of the CompStashDone response are generated as follows:

- The TgtID is set to the same value as the SrcID of the request.
- The TxnID is set to the same value as the TxnID of the request.
- The StashGroupID is set to the same value as the StashGroupID of the request.

4. The Home Node in the interconnect generates a snoop with Stash to the appropriate RN-F.

The identifier fields of the request are generated as follows:

- The SrcID is a fixed value for the Home.
- The TxnID is a unique value generated by the Home.
- The StashLPID is set to the same value as the StashLPID of the original request.

Note

A Snoop request does not include a TgtID field.

5. The snooped RN-F generates a Snoop response. In this example, it includes a Data Pull indication.

The identifier fields of the Snoop response are generated as follows:

- The TgtID is set to the same value as the SrcID of the request.
- The SrcID is a fixed value for the RN-F.
- The TxnID is set to the same value as the TxnID of the request.
- The DBID field is a unique value generated by the RN-F.

6. The Home provides the read data.

The identifier fields of the read Data response are generated as follows:

- The TgtID is set to the same value as the SrcID of the Snoop response.
- The SrcID is a fixed value for the Home.

Note

In this example, the read data is being provided by the Home.

- The TxnID is set to the same value as the DBID of the Snoop response.
- The DBID field is a unique value generated by Home.
- The HomeNID is a fixed value for the Home.

7. The RN-F receives the read data and sends a completion acknowledge, CompAck, response.

The identifier fields of the CompAck are generated as follows:

- The TgtID is set to the same value as the HomeNID of the read data.
- The SrcID is a fixed value for the RN-F. This also matches the TgtID received.
- The TxnID is set to the same value as the DBID of the read data.
- The DBID field is not valid.

2.5.4 DVMOp transaction

The use of the TgtID, SrcID, TxnID, and DBID identifier fields for a DVMOp transaction is identical to that for the *WriteNoSnp transaction*.

2.5.5 Transaction requests with Retry

For transactions that receive a RetryAck response, there are specific rules on how the identifier fields are used. See *Request Retry* on page 2-154, for more details on the Retry mechanism, and *Protocol Credit Return transaction*, for rules about the return of unused credits.

Figure 2-33 shows the identifier value transfer.

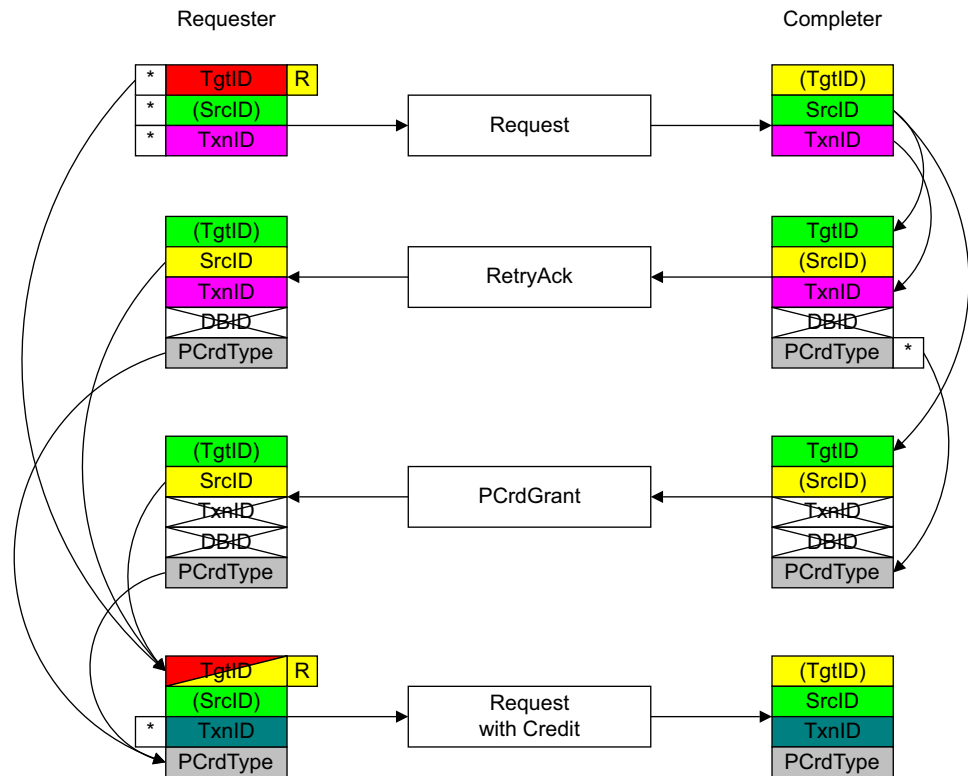

Figure 2-33 ID value transfer in a transaction request with retry

The required steps in the flow that Figure 2-33 shows are:

- The Requester starts the transaction by sending a Request packet. The identifier fields of the request are generated as follows:
 - The TgtID is determined by the destination of the Request.

———— Note ————

The TgtID field can be remapped to a different value by the interconnect.

 - The SrcID is a fixed value for the Requester.
 - The Requester generates a unique TxnID field.

2. The Completer receives the Request packet and determines that it is going to send a RetryAck response. The identifier fields of the RetryAck response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Completer. This also matches the TgtID received.
 - The TxnID is set to the same value as the TxnID of the request.
 - The DBID field is not valid.
 - The Completer uses a PCrdType value that indicates the type of credit required to retry the transaction.
3. When the Completer is able to accept the retried transaction of a given PCrdType it sends a credit to the Requester, using the PCrdGrant response. The identifier fields of the PCrdGrant response are generated as follows:
 - The TgtID is set to the same value as the SrcID of the request.
 - The SrcID is a fixed value for the Completer. This also matches the TgtID of the request.
 - The TxnID field is not used and must be set to zero.
 - The DBID field is not used and must be set to zero.
 - The PCrdType value is set to the type required to issue the original transaction again.
4. The Requester receives the credit grant and reissues the original transaction by sending a Request packet. The identifier fields of the request are generated as follows:
 - The TgtID is set to either the same value as the SrcID of the RetryAck response, which is also the same as the SrcID of the PCrdGrant response, or the value used in the original request.
 - The SrcID is a fixed value for the Requester.
 - The Requester generates a unique TxnID field. This is permitted, but not required, to be different from the original request that received a RetryAck response.
 - The PCrdType value is set to the PCrdType value in the RetryAck response to the original request, which is also the same as the PCrdType of the PCrdGrant response.

2.5.6 Protocol Credit Return transaction

A P-Credit Return transaction uses the PCrdReturn Request to return a granted, but no longer required, credit. The TgtID, SrcID, and TxnID requirements are:

- The Requester sends the Protocol Credit Return transaction by sending a PCrdReturn Request packet. The identifier fields of the request are generated as follows:
 - The TgtID must match the SrcID of the credit that was obtained.
 - The SrcID is a fixed value for the Requester.
 - The TxnID field is not used and must be set to zero.

The PCrdType must match the value of the PCrdType in the original PCrdGrant that was required to issue the original transaction again.

There is no response or use made of the DBID field associated with Protocol Credit Return transactions.

2.6 Ordering

This section describes the mechanisms that the protocol includes to support system ordering requirements. It contains the following subsections:

- [Multi-copy atomicity](#)
- [Completion response and ordering](#)
- [Completion acknowledgment on page 2-123](#)
- [Transaction ordering on page 2-125](#)

For the meaning of the terms EWA, Device, and Cacheable see [Memory Attributes on page 2-134](#).

2.6.1 Multi-copy atomicity

The memory model used in this specification requires multi-copy atomicity. All compliant components must ensure that all write-type requests are multi-copy atomic. A write is defined as multi-copy atomic if both of the following conditions are true:

- All writes to the same location are serialized, that is, they are observed in the same order by all Requesters, although some Requesters might not observe all of the writes.
- A read of a location does not return the value of a write until all Requesters observe that write.

In this specification, two addresses are considered to be the same with respect to coherence, observability, and hazarding if their cache line addresses and NS attribute are the same.

2.6.2 Completion response and ordering

[Table 2-7](#) shows the Comp, RespSepData, CompData, or Persist response, which guarantees the ordering of a transaction with respect to later transactions, either from the same agent or from another agent.

Table 2-7 Completion response and ordering

Transaction	Location	Response	Outcome
Read	Cacheable	CompData or DataSepResp	The transaction is observable to a later transaction from any agent to the same location.
	Cacheable	RespSepData	No earlier transaction will send a snoop to this Requester. All later transactions will send a snoop only if required after the Home receives the CompAck response for this transaction.
	Non-cacheable or Device	RespSepData or CompData	The transaction is observable to a later transaction from any agent to the same endpoint address range.
Write or Atomic	Cacheable	Comp or CompData	The transaction is observable to a later transaction from any agent to the same location.
	Non-cacheable or Device	Comp or CompData	The transaction is observable to a later transaction from any agent to the same endpoint range.
Dataless except for StashOnceSep		Comp	The transaction is observable to a later transaction from any agent to the same memory location.
CleanSharedPersist		Comp	Any data written earlier to the same memory location is made persistent.

Table 2-7 Completion response and ordering (continued)

Transaction	Location	Response	Outcome
Combined Write		CompCMO	CMO, PCMO, and write operations are observable to a later transaction from any agent to the same memory location.
		Comp	The write operation is observable to a later transaction from any agent to the same endpoint address range.
CleanSharedPersistSep		Persist	The data written earlier to the same memory location is made persistent.
Combined Write with Persistent CMO		Persist	The data write in the Combined Write is made persistent. All earlier writes on the same line will also be made persistent.
StashOnceSep		Comp	The Completer accepts the request and will not send a RetryAck response.
		StashDone	The transaction is observable to a later transaction from any agent to the same memory location.

Note

The size of the endpoint address range is IMPLEMENTATION DEFINED.

In a combined *Ordered Write Observation* (OWO) Write request, if the write is canceled, that is, the Requester sends a WriteDataCancel, then the required cache maintenance on the write data is not carried out. The Requester must resend both the Write request and the CMO:

- If the combined request that had its write canceled is a Write with PCMO:
 - The Persist response for the combined request does not indicate that the write data is made persistent.
 - The Requester must resend the PCMO either combined with the resent Write request or after the resent Write request succeeds.
- If the combined request that had its write canceled is a Write with CMO:
 - The Requester must resend the CMO, either combined with the re-sent Write request or after the resent Write request succeeds.

Note

The size of an endpoint address range is IMPLEMENTATION DEFINED. Typically, this is:

- The size of a peripheral device, for a region used for peripherals.
- The size of a cache line, for a region used for memory.

A Cacheable location can be determined by the assertion of the MemAttr[2] Cacheable bit in the request. A Non-cacheable or Device location can be determined by the deassertion of the MemAttr[2] Cacheable bit in the request.

A component must only give a Comp or CompDBIDResp response when it is guaranteed that all observers will see the result of the atomic operation.

A Comp response in a canceled write only implies that the transaction loop is completed and makes no statement regarding the completion of coherency action initiated by the write. Therefore, the Completer is permitted to send a Comp as soon as it receives a WriteDataCancel response without dependency on either the processing of the write request or the completion of any snoops sent due to the write.

2.6.3 Completion acknowledgment

The relative ordering of transactions issued by a Requester, and Snoop transactions caused by transactions from different Requesters, is controlled by the use of a completion acknowledgment, CompAck, response. This ensures that a Snoop transaction that is ordered after the transaction from the Requester is guaranteed to be received after the transaction response.

The sequencing of the completion of a Read transaction and the sending of CompAck is as follows:

1. An RN-F sends a CompAck after receiving Comp, RespSepData, or CompData, or both RespSepData and DataSepResp.
2. An HN-F, except in the case of ReadOnce*, waits for CompAck before sending a subsequent snoop to the same address. For CopyBack transactions, WriteData acts as an implicit CompAck and an HN-F must wait for WriteData before sending a snoop to the same address.

This sequence guarantees that an RN-F receives completion for a transaction and a snoop to the same cache line in the same order as they are sent from an HN-F. This ensures transactions to the same cache line are observed in the correct order.

When an RN-F has a transaction in progress that uses CompAck, except for ReadNoSnp and ReadOnce*, it is guaranteed not to receive a Snoop request to the same address between the point that it receives Comp and the point that it sends CompAck.

For WriteNoSnp and WriteUnique transactions that require a CompAck message, a Request Node sends the CompAck after receiving the Comp, DBIDResp, or CompDBIDResp response.

The use of CompAck for a transaction is determined by the Requester setting the ExpCompAck field in the original request. The rules for a Request Node setting the ExpCompAck field and generating a CompAck response are as follows:

- An RN-F must include a CompAck response in all Read transactions except ReadNoSnp and ReadOnce*.
- An RN-F is permitted, but not required, to include a CompAck response in ReadNoSnp and ReadOnce* transactions.
- An RN-F must not include a CompAck response in StashOnce*, CMO, Atomic, or Evict transactions.
- An RN-I or RN-D is permitted, but not required, to include a CompAck response in Read transactions.
- An RN-I or RN-D must not include a CompAck response in Dataless or Atomic transactions.
- A Request Node that wants to make use of DMT must include a CompAck response in ordered ReadNoSnp and ReadOnce* transactions.
- For Write transactions, CompAck can only be used for WriteUnique and WriteNoSnp transactions when they require Ordered Write Observation guarantees. See [Streaming Ordered Write transactions on page 2-129](#).
- For WriteEvictOrEvict, ExpCompAck must be set to one indicating the transaction will include a CompAck when the Completer sends a Comp instead of a CompDBIDResp.

For transactions between a Request Node and a Home Node, where the Home Node is the Completer, the Home Node must support the use of CompAck for all transactions that are required or permitted to use CompAck.

A Subordinate Node is not required to support the use of CompAck.

A Requester, such as an HN-F or HN-I that communicates with an SN-F or SN-I respectively, must not send a CompAck response.

[Table 2-8 on page 2-124](#) shows the Request types that require a CompAck response and the corresponding Requester types that are required to provide that response. The following key is used:

Y	Yes, required
N	No, not required
O	Optional

- Not applicable

Table 2-8 Requester CompAck requirement

Request type	CompAck Required	
	RN-F	RN-D, RN-I
ReadNoSnP	O	O
ReadOnce*	O	O
ReadClean	Y	-
ReadNotSharedDirty	Y	-
ReadShared	Y	-
ReadUnique	Y	-
ReadPreferUnique	Y	-
MakeReadUnique	Y	-
CleanUnique	Y	-
MakeUnique	Y	-
CleanShared	N	N
CleanSharedPersist*	N	N
CleanInvalid	N	N
MakeInvalid	N	N
WriteBack	N	-
WriteClean	N	-
WriteUnique	O	O
WriteUniqueZero	N	N
Evict	N	-
WriteEvictFull	N	-
WriteEvictOrEvict	Y	-
WriteNoSnP	O	O
WriteNoSnPZero	N	N
Atomics	N	N
StashOnce*	N	N

In a Combined Write transaction, the CompAck requirement is the same as the CompAck requirement for the type of Write in the Combined Write transaction.

2.6.4 Ordering semantics of RespSepData and DataSepResp

When a Requester receives the first DataSepResp, it can consider the Read transaction to be globally observed. This is because there is no action which can modify the read data received.

When a Requester receives a RespSepData response from Home, the request that it applies to has been ordered at Home and the Requester will not receive any snoops for transactions that are scheduled before it. Before sending RespSepData response to the Requester, the Home must ensure that no Snoop transactions are outstanding to that Requester to the same address. Receiving of RespSepData does not guarantee that Home has completed snooping of other agents in the system.

When the Requester gives a completion acknowledge, CompAck, response, this Requester is indicating that it will accept responsibility to hazard snoops for any transaction that is scheduled after it. The following rules apply:

- For all transactions, except as described immediately below, the CompAck must be sent after the RespSepData response is received. It is permitted, but not required, to wait for the DataSepResp response before the CompAck is given.
- For ReadOnce and ReadNoSnp transactions with an ordering requirement, that is, Order field is set to 0b10 or 0b11 and ExpCompAck field is asserted, it is required that the CompAck is given only after both DataSepResp and RespSepData responses are received.
- The Requester must wait to receive both RespSepData and DataSepResp before issuing another request to the same address.

Note

It is required that CompAck must not be given when only DataSepResp is received.

2.6.5 Transaction ordering

In addition to using a Comp response to order a sequence of requests from a Requester, this specification also defines mechanisms for ordering of requests between a Request Node, Home Node pair and an HN-I, SN-I pair. Between an HN-F, SN-F pair and HN-I, SN-I pair, the order field is used to obtain a Request Accepted acknowledgment.

Requester Order between an RN, HN pair and an HN-I, SN-I pair is supported by the Order field in a request. The Order field indicates that the transaction requires one of the following forms of ordering:

Request Order

This guarantees the order of multiple transactions, from the same agent, to the same address location.

Endpoint Order

This guarantees the order of multiple transactions, from the same agent, to the same endpoint address range.

Ordered Write Observation, OWO

This guarantees the observation order by other agents in the system, for a sequence of Write transactions from a single agent.

Request Accepted

This guarantees that the Completer will send a positive acknowledgment only when it has accepted the Read request.

Table 2-9 shows the Order field encodings.

Table 2-9 Order value encodings

Order[1:0]	Description	Permitted between
0b00	No ordering required	All
0b01	Request accepted	HN-F to SN-F and HN-I to SN-I
	Reserved	RN to HN
0b10	Request Order/Ordered Write Observation	RN to HN ^a
	Request Order	HN-I to SN-I
	Reserved	HN-F to SN-F
0b11	Endpoint Order	RN to HN and HN-I to SN-I
	Reserved	HN-F to SN-F

- a. Request Order when ExpCompAck = 0.
Ordered Write Observation when ExpCompAck = 1.

Ordering requirements

A Requester that changes the ordering requirements of a transaction to a stronger ordering requirement is required to be consistent in changing the ordering requirement of Request Order to Endpoint Order on all its transactions.

The Order field must only be set to a non-zero value for the following transactions:

- ReadNoSnP
- ReadNoSnPSeq
- ReadOnce*
- WriteNoSnP
- WriteNoSnP*CMO
- WriteNoSnPZero
- WriteUnique
- WriteUnique*CMO
- WriteUniqueZero
- Atomic

When a ReadNoSnP or ReadOnce* transaction requires Request Order or Endpoint Order:

- The Requester requires a ReadReceipt to determine when it can send the next ordered request.
- At the Completer, a ReadReceipt means the request has reached the next ordering point that will maintain requests in the order they were received:
 - For requests that require Request Order, it will maintain order between requests to the same address from the same source.
 - For requests that require Endpoint Order, it will maintain order between requests to the same endpoint address range from the same source.
- A Completer that is capable of sending separate Non-data and Data-only responses can send RespSepData response instead of ReadReceipt and achieve the same functional behavior.

When a WriteNoSnP, WriteNoSnPZero, or a Non-snooppable Atomic transaction requires Request Order or Endpoint Order:

- The Requester requires a DBIDResp or DBIDRespOrd to determine when it can send the next ordered request.

- The Completer sending a DBIDResp or DBIDRespOrd response means that a data buffer is available and the Write request has reached a PoS that will maintain requests in the order they were received:
 - For requests that require Request Order, it will maintain order between requests to the same address from the same source.
 - For requests that require Endpoint Order, it will maintain order between requests to the same endpoint address range from the same source.

When a WriteUnique transaction without ExpCompAck asserted, or a WriteUniqueZero or a Snoopable Atomic transaction require Request Order:

- The Requester requires a DBIDResp or DBIDRespOrd to determine when it can send the next ordered request.
- The Completer sending a DBIDResp or DBIDRespOrd response means that it will maintain order between requests to the same address from the same source.

Additionally, when a Completer sends DBIDRespOrd for a request with a no order or Request Order requirement, the Completer guarantees to order all subsequent no order or Request Order received requests to the same address from the same source against this request, where these later received requests are of any transaction type, not necessarily Write transactions. When the write includes a CMO, the order is guaranteed against both the write and the CMO.

When a WriteUnique or WriteNoSnp transaction requires Ordered Write Observation:

- CompAck is required. The Request Node must assert ExpCompAck.
- The Request Node requires a DBIDResp or DBIDRespOrd.
- The Completer is a PoS. A PoS sending DBIDResp or DBIDRespOrd means:
 - A data buffer is available.
 - The PoS guarantees that the completion of the coherence action on this write does not depend on completion of the coherence action on a subsequent write that requires Ordered Write Observation.
 - The write is not made visible until CompAck is received.

All architectural mechanisms applicable to increasing streaming efficiency and corresponding constraints are defined in [Streaming Ordered Write transactions on page 2-129](#).

When a ReadNoSnp or ReadNoSnpSep has the Order field set to 0b01, a ReadReceipt response from the Completer guarantees that the Completer has accepted the request and will not send a RetryAck response.

Read Request Order example

Figure 2-34 shows the request ordering of three Read requests.

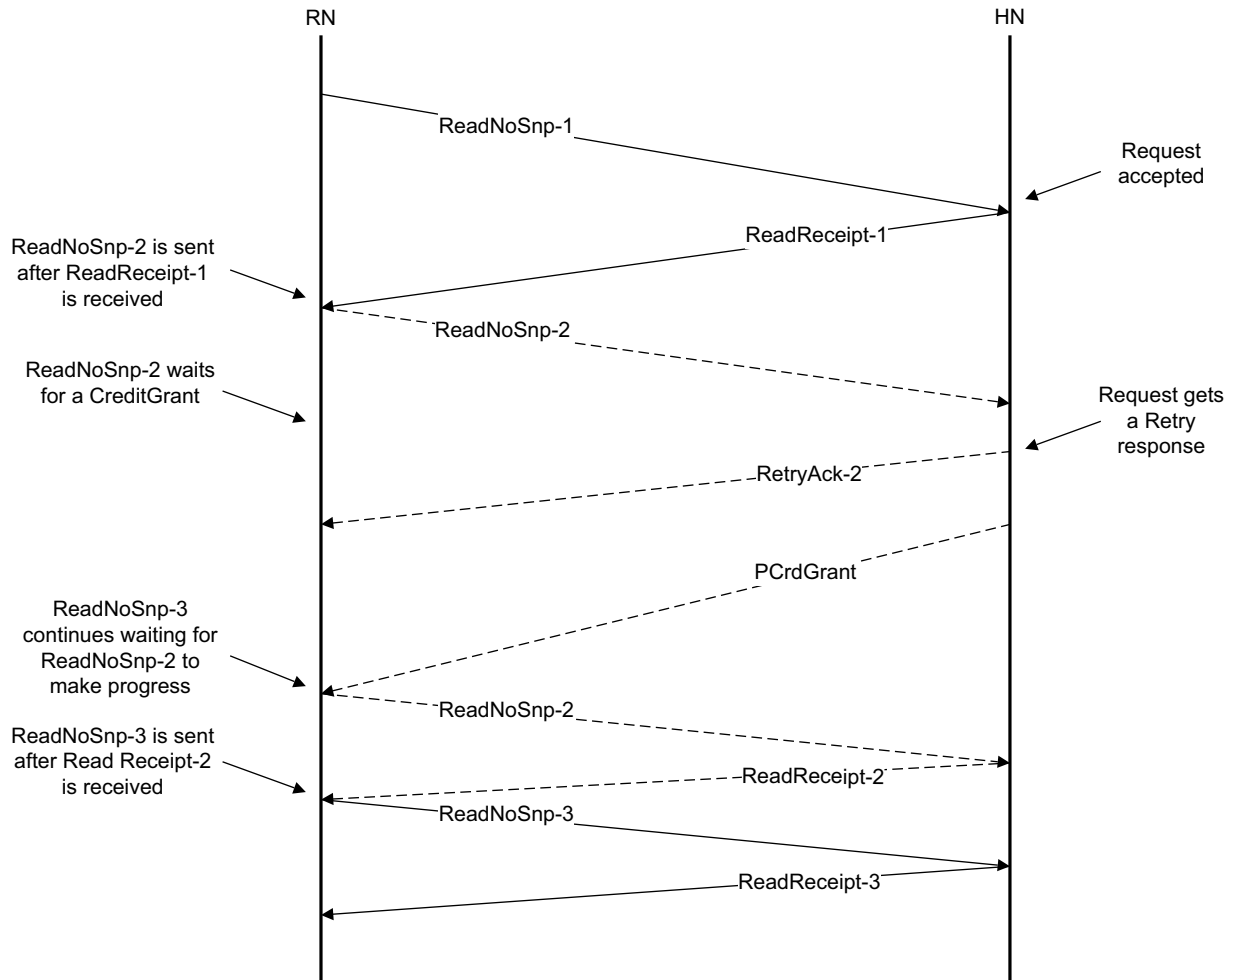

Figure 2-34 Series of ordered Read requests

Three ordered requests are sent from Request Node to Home Node in Figure 2-34 as follows:

1. The Request Node sends the ReadNoSnp-1 request to the Home Node.
2. The Home Node accepts the request and returns the ReadReceipt-1 response to the Request Node.
3. After the ReadReceipt-1 response is received, the Request Node sends the ReadNoSnp-2 request to the Home Node.
4. The Home Node cannot immediately accept the ReadNoSnp-2 request and returns the RetryAck-2 response to the Request Node.
5. The Request Node must now wait for a PCrdGrant to be sent from the Home Node before resending the ReadNoSnp-2 request. The Request Node does not send ReadNoSnp-3 at this point, as it wants to order ReadNoSnp-3 behind ReadNoSnp-2. This ordering requires that ReadNoSnp-2 must be accepted at the Home Node before ReadNoSnp-3 is sent to the Home Node.
6. After receipt of an appropriate PCrdGrant, the Request Node resends the ReadNoSnp-2 request.
7. The Home Node accepts the request and returns a ReadReceipt-2 response to the Request Node.

8. After receipt of the ReadReceipt-2 response, the Request Node sends the ReadNoSnp-3 request to the Home Node.
9. The Home Node accepts the request and returns the ReadReceipt-3 response to the Request Node.
10. Each of the read transactions is completed with Requester receiving a completion and data. This is not shown in Figure 2-34 on page 2-128.

Note

Figure 2-34 on page 2-128 shows a single ordered stream of three reads from the Request Node. However, a Request Node can have multiple streams of reads, so requests must be ordered within a stream. However, ordering dependency does not exist between streams. One example of this is when the streams are from different threads within the Request Node. In this case, the Request Node waits for the ReadReceipt of the previous request from the same thread only before sending out the next ordered request from that stream.

CopyBack Request order

An RN-F must wait for the CompDBIDResp response to be received for an outstanding CopyBack transaction before issuing another request to the same cache line. It is permitted, but not required, for an Atomic transaction with SnoopMe asserted to be issued before the CompDBIDResp response is received for an outstanding CopyBack to the same cache line.

Streaming Ordered Write transactions

The architectural mechanisms applicable to increasing *Ordered Write Observation* (OWO) Write streaming efficiency, and the corresponding constraints, are applicable to WriteUnique and WriteNoSnp transactions only. If a Requester requires a sequence of Write transactions to be observed in the same order as they are issued, the Requester can wait for completion before issuing the next write in the sequence. Such an observation ordering is typically termed OWO.

This specification provides a mechanism termed Streaming Ordered Writes to more efficiently stream such ordered Write transactions.

The Streaming Ordered Write mechanism relies on the use of the OWO ordering requirement and CompAck. Responsibilities of Requesters and HN-F when utilizing the Streaming Ordered Write solution are:

- The Requester must set the Order field to 0b10 and set ExpCompAck on the Write request.
- The OWO requirement in a Write request indicates to the HN-F that the completion of coherence action on this write must not depend on completion of coherence action on a subsequent write.
- The Requester must wait for DBIDResp, DBIDRespOrd, CompDBIDResp, or Comp for a Write transaction before sending the next Write request.
- The Requester must send a CompAck response after receiving DBIDResp, DBIDRespOrd, CompDBIDResp, or Comp responses for the corresponding writes and Comp or CompDBIDResp responses for all earlier related ordered writes. If write data is to be sent, the Requester is permitted, but not required, to combine the CompAck response with the WriteData response into a NCBWrDataCompAck response. When the Requester uses the combined CompAck and WriteData response for a transaction, it must send a combined response for all WriteData transfers in that transaction. The method by which a Requester determines if a group of ordered writes are related is IMPLEMENTATION DEFINED.

Note

Waiting to send CompAck response until all prior writes have received their Comp responses ensures the operations at the respective HN-Fs have completed. Any Requester observing the write associated with the CompAck response will also observe all prior ordered writes.

- The Requester that receives DBIDResp* and is ready to send CompAck must not wait for Comp to send CompAck.

- HN-F must wait for a CompAck response from the Request Node before deallocating a Write transaction and making the write visible to other observers.

Optimized Streaming Ordered Write transactions

The writes in this section refer to WriteUnique or WriteNoSnp only. The Streaming Ordered Writes mechanism can be further optimized. If a previously sent write is to a different target, the Requester does not need to wait for the DBIDResp* for the request before sending the next ordered write. However, if the interconnect can remap the TgtID, the Requester must presume that all Write transactions are targeting the same HN-F and must not use the optimized version of the Streaming Ordered Writes flow.

An implementation using an optimized or non-optimized Streaming Ordered Writes solution must avoid deadlock and livelock situations.

Note

A technique for avoiding resource-related deadlock or livelock issues is to limit Streaming Ordered Writes optimization to one Requester in the system. All other Requesters in the system can use the Streaming Ordered Writes solution without the optimization.

In a typical system, the optimized Streaming Ordered Writes solution is most beneficial to an RN-I that is a conduit for PCIe style, non-relaxed order, Snoopable writes. In most systems, one RN-I hosting this type of PCIe traffic is adequate.

OWO Writes can be used by more than one Requester by making use of WriteDataCancel messages to avoid resource related deadlocks and livelocks.

Figure 2-35 shows a typical transaction flow in which an RN-I uses Streaming Ordered WriteUnique transactions. This flow prevents a read acquiring the new value of Write-B before Write-A has completed.

Note

For clarity, the Write-B DBIDResp* and the NCBWrData flow is omitted from Figure 2-35.

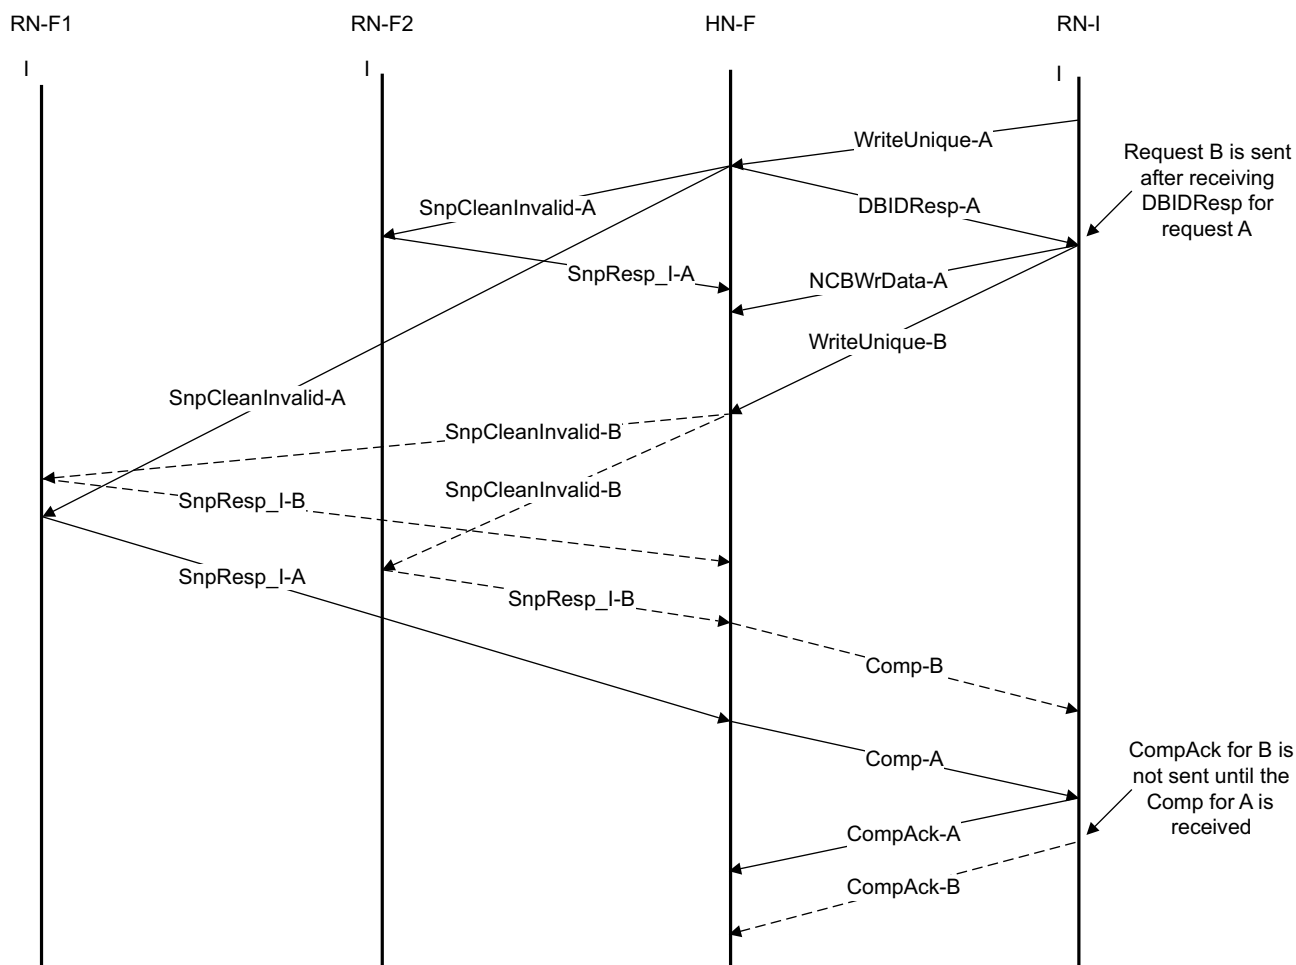

Figure 2-35 Streaming Ordered WriteUnique transactions flow

The Streaming Ordered WriteUnique transaction flow is as follows:

1. RN-I issues WriteUnique-A to the Home.
2. The Home responds with DBIDResp and issues SnpCleanInvalid-A to RN-F1 and RN-F2.
3. RN-I sends the write data associated with WriteUnique-A and issues the next ordered WriteUnique request to the Home, shown in Figure 2-35 as WriteUnique-B.
4. WriteUnique-A and WriteUnique-B are to different addresses. The Home sends out SnpCleanInvalid-B snoops to RN-F1 and RN-F2 for WriteUnique-B without waiting for responses for WriteUnique-A transaction snoops.
5. The Snoop responses for the WriteUnique-B transaction are received by the Home before the Snoop responses for the WriteUnique-A transaction are received. Home sends Comp to RN-I for the WriteUnique-B transaction.

6. The Home waits for Snoop responses for the WriteUnique-A transaction to be received. Once received, the Home can send Comp to RN-I for the WriteUnique-A transaction.
7. The Requester, RN-I, receives Comp-B and waits to receive Comp-A before proceeding with the next response.
8. Once the RN-I receives Comp-A, it sends the corresponding CompAck response for the WriteUnique-A transaction, followed by a CompAck response for the WriteUnique-B transaction.

2.7 Address, Control, and Data

A transaction includes attributes defining the manner in which the transaction is handled by the interconnect. These include the address, memory attributes, snoop attributes, and data formatting. Each attribute is defined in this section.

In this section, unless explicitly stated otherwise, a reference to a Write transaction includes both the individual Write transaction and the corresponding Combined Write transaction.

2.7.1 Address

This specification supports:

- *Physical Address (PA)* of 44 to 52 bits, in one bit increments.
- *Virtual Address (VA)* of 49 to 53 bits.

The REQ and SNP packet Addr fields are specified as follows:

- REQ channel: Address[(MPA-1):0]
- SNP channel: Address[(MPA-1):3]

MPA is the Maximum PA supported.

Table 2-10 shows the relationship between the physical address field width and the supported virtual address.

Table 2-10 Addr field width and supported PA and VA size

REQ Addr field width in bits	Maximum address supported in bits	
	PA	VA
44	44	49
45	45	51
46 to 52	46 to 52	53

See *DVMOp and SnpDVMOp packet* on page 8-325 for DVM payload mapping in the REQ and SNP fields with different Addr field widths.

The Req_Addr_Width parameter is used to specify the maximum physical address in bits that is supported by a component. Valid values for this parameter are 44 to 52, when not specified, the parameter takes the default value of 44.

2.7.2 Non-secure bit

Secure and Non-secure transactions are defined to support Secure and Non-secure operating states.

This bit is defined so that when it is asserted the transaction is identified as a Non-secure transaction.

For Snooper transactions, this field can be considered as an additional address bit that defines two address spaces: a Secure address space and a Non-secure address space. Any aliasing between the Secure and Non-secure address spaces must be handled correctly.

————— Note —————

Hardware coherency does not manage coherency between Non-Secure and Secure address spaces.

The Non-secure assertion requirements are:

- Can be asserted in any Read, Dataless, Write, and Atomic transaction.
- Can be asserted in PrefetchTgt transaction.
- Is not applicable in the DVMOp or PCrdReturn transaction, and must be set to zero.

2.7.3 Memory Attributes

The *Memory Attributes* (MemAttr) consist of *Early Write Acknowledgment* (EWA), Device, Cacheable, and Allocate.

EWA

EWA indicates whether the Write completion response for a transaction:

- Can come from an intermediate point in the interconnect, such as a Home Node.
- Must come from the final endpoint at the target destination.

If EWA is asserted, the Write completion response for the transaction can come from an intermediate point or from the endpoint. A completion that comes from an intermediate point must provide the same guarantees required by a Comp as described in [Completion response and ordering on page 2-121](#).

If EWA is deasserted, the write completion response for the transaction must come from the endpoint.

———— Note ————

It is permitted, but not required, for an implementation not to use the EWA attribute. In this instance, completion must be given from the endpoint.

The EWA assertion requirements:

- Can take any value in:
 - A ReadNoSnp and ReadNoSnpSep transaction
 - A WriteNoSnp transaction.
 - CMO transactions.
 - Atomic transactions.
- Must be asserted in any:
 - Read transaction that is not a ReadNoSnp or ReadNoSnpSep transaction.
 - Dataless transaction that is not a CMO transaction.
 - Write transaction that is not a WriteNoSnp transaction.
- Is inapplicable and:
 - Must be set to zero in the DVMOp or PCrdReturn transactions.
 - Can take any value in the PrefetchTgt transaction.

Device

Device attribute indicates if the memory type is either Device or Normal.

Device memory type

Device memory type must be used for locations that exhibit side-effects. Use of Device memory type for locations that do not exhibit side-effects is permitted.

The requirements for a transaction to a Device type memory location are:

- A Read transaction must not read more data than requested.
- Prefetching from a Device memory location is not permitted.
- A read must get its data from the endpoint. A read must not be forwarded data from a write to the same address location that completed at an intermediate point.
- Combining requests to different locations into one request, or combining different requests to the same location into one request, is not permitted.
- Writes must not be merged.
- Writes to Device memory that obtain completion from an intermediate point must make the write data visible to the endpoint in a timely manner.

Accesses to Device memory must use the following types, exclusive variants are permitted:

- Read accesses to a Device memory location must use ReadNoSnp.
- Write accesses to a Device memory location must use either WriteNoSnpFull or WriteNoSnpPtl.
- CMO transactions are permitted to Device memory locations.
- Atomic transactions are permitted to Device memory locations.
- The PrefetchTgt transaction is not permitted to Device memory locations. The MemAttr field is inapplicable and can take any value in the PrefetchTgt transaction.

Normal memory type

Normal memory type is appropriate for memory locations that do not exhibit side-effects.

Accesses to Normal memory do not have the same restrictions regarding prefetching or forwarding as Device type memory:

- A Read transaction that has EWA asserted can obtain read data from a Write transaction that has sent its completion from an intermediate point and is to the same address location.
- Writes can be merged.

Any Read, Dataless, Write, PrefetchTgt, or Atomic transaction type can be used to access a Normal memory location. The transaction type used is determined by the memory operation to be accomplished, and the Snoopable attributes.

Cacheable

The Cacheable attribute indicates if a transaction must perform a cache lookup:

- When Cacheable is asserted, the transaction must perform a cache lookup.
- When Cacheable is deasserted, the transaction must access the final destination.

The Cacheable attribute value requirements:

- Must be asserted for any:
 - Read transaction except ReadNoSnp and ReadNoSnpSep.
 - Dataless transaction except CleanShared, CleanSharedPersist*, CleanInvalid, and MakeInvalid.
 - Write transaction, except WriteNoSnpFull and WriteNoSnpPtl.
- Must not be asserted for any device memory transaction.
- Can take any value for:
 - ReadNoSnp or ReadNoSnpSep transaction to a Normal memory location.
 - WriteNoSnpFull and WriteNoSnpPtl transactions to a Normal memory location.
 - CleanShared, CleanSharedPersist*, CleanInvalid, and MakeInvalid.
 - An Atomic transaction.
- Is inapplicable and:
 - Must be set to zero in DVMOp and PCrdReturn.
 - Can take any value in the PrefetchTgt.

———— Note ————

In a transaction that can take any Cacheable value, the value is typically determined from the page table attributes.

Allocate

The Allocate attribute is an allocation hint and indicates the recommended allocation policy for a transaction:

- If Allocate is asserted, it is recommended that the transaction is allocated into the cache for performance reasons. However, it is permitted to not allocate the transaction.
- If Allocate is deasserted, it is recommended that the transaction is not allocated into the cache for performance reasons. However, it is permitted to allocate the transaction.

The Allocate attribute value requirements:

- Can be asserted for transactions that have the Cacheable attribute asserted, except for ReadOnceMakeInvalid.
- Must be asserted for the WriteEvictFull transaction.

———— Note ————

A Requester can convert a WriteEvictFull with the Allocate bit not asserted to an Evict transaction.

- Must not be asserted for:
 - Device memory transactions.
 - Normal Non-cacheable memory transactions.
- Is inapplicable and:
 - Must be set to zero in DVMOp, PCrdReturn, and Evict transactions.
 - Can take any value in the PrefetchTgt transaction.

Propagation of Attr

A request from the Home Node to Subordinate Node sent in response to a request to the Home Node must preserve the MemAttr bits EWA, Device, Cacheable, and Allocate. The only exception to this rule is when the downstream memory is known to be Normal, then the Device field value can be set to 0b0 to indicate Normal.

In a Combined Write transaction, when the write and CMO transactions are separated, the Write transaction inherits the MemAttr and SnpAttr values of the original combined request. The separated CMO transaction SnpAttr and Cacheable bits must be set to the most pervasive to affect all caches at RN-F nodes and caches downstream.

For a ReadNoSnp or WriteNoSnp generated within the interconnect due to a Prefetch from Home or an eviction from the System cache:

- MemAttr bits EWA, Cacheable, and Allocate must all be set to 0b1.
- Device field value must be set to 0b0 to indicate Normal.
- SnpAttr field value must be set to 0b0 to indicate Non-snoopable.

2.7.4 Transaction attribute combinations

Table 2-11 lists the legal combinations of MemAttr, SnpAttr, and Order field values and the equivalent ARM memory type. The Order field is described in [Ordering on page 2-121](#).

Table 2-11 Legal combinations of MemAttr, SnpAttr, and Order field values

MemAttr[3:0]						Order[1:0]		ARM Memory Type
Device	Allocate	Cacheable	EWA	SnpAttr	LikelyShared	[1]	[0]	
						[1]	[0]	
1	0	0	0	0	0	1	1	Device nRnE
	0	0	1	0	0	1	1	Device nRE
	0	0	1	0	0	0/1 ^a	0	Device RE
	All other values ^b					Not valid		
0	0	0	0	0	0	0/1 ^a	0	Non-cacheable Non-bufferable ^c
	0	0	1	0	0	0/1 ^a	0	Non-cacheable Bufferable
	0	1	1	0	0	0/1 ^a	0	Non-snoopable WriteBack No-allocate
	1	1	1	0	0	0/1 ^a	0	Non-snoopable WriteBack Allocate
	0	1	1	1	0/1 ^d	0/1 ^a	0	Snoopable WriteBack No-allocate
	1	1	1	1	0/1 ^d	0/1 ^a	0	Snoopable WriteBack Allocate
All other values ^b						Not valid		

a. Order = 0b10 is permitted, but not required, in ReadOnce*, WriteUnique, ReadNoSnp, WriteNoSnp and Atomic transactions only.

b. Order = 0b01 is not used for transactions' ordering. See [Transaction ordering on page 2-125](#).

c. Non-cacheable Non-bufferable is an AXI memory type, not an ARM memory type.

d. See [Likely Shared on page 2-139](#).

Memory type

This section specifies the required behavior for each of the memory types shown in [Table 2-11 on page 2-137](#).

Device nRnE

The required behavior for Device nRnE memory type is:

- The write response must be obtained from the final destination.
- Read data must be obtained from the final destination.
- A read must not fetch more data than is required.
- A read must not be prefetched.
- Writes must not be merged.
- A write must not write to a larger address range than the original transaction.
- All Read and Write transactions from the same source to the same endpoint must remain ordered.

Device nRE

The required behavior for the Device nRE memory type is the same as for the Device nRnE memory type, except that the write response can be obtained from an intermediate point.

Device RE

The required behavior for the Device RE memory type is same as for the Device nRE memory type, except:

- Read and Write transactions from the same source to the same endpoint need not remain ordered.
- Read and Write transactions from the same source to addresses that overlap must remain ordered.

Normal Non-cacheable Non-bufferable

The required behavior for the Normal Non-cacheable Non-bufferable memory type is:

- The write response must be obtained from the final destination.
- Read data must be obtained from the final destination.
- Writes can be merged.
- Read and Write transactions from the same source to addresses that overlap must remain ordered.

Normal Non-cacheable Bufferable

The required behavior for the Normal Non-cacheable Bufferable memory type is:

- The write response can be obtained from an intermediate point.
- Write transactions must be made visible at the final destination in a timely manner.

———— **Note** —————

There is no mechanism to determine when a Write transaction is visible at its final destination.

- Read data must be obtained either from:
 - The final destination.
 - A Write transaction that is progressing to its final destination.If read data is obtained from a Write transaction:
 - It must be obtained from the most recent version of the write.
 - The data must not be cached to service a later read.
- Writes can be merged.
- Read and Write transactions from the same source to addresses that overlap must remain ordered.

———— **Note** —————

For a Normal Non-cacheable Bufferable read, data can be obtained from a Write transaction that is still progressing to its final destination. This is indistinguishable from the Read and Write transactions propagating to arrive at the final destination at the same time. Read data returned in this manner does not indicate that the Write transaction is visible at the final destination.

Write-Back No-allocate

The required behavior for the Write-Back No-allocate memory type is:

- The Write response can be obtained from an intermediate point.
- Write transactions are not required to be made visible at the final destination.
- Read data can be obtained from an intermediate cached copy.
- Reads can be prefetched.
- Writes can be merged.
- A cache lookup is required for Read and Write transactions.
- Read and Write transactions from the same source to addresses that overlap must remain ordered.
- The No-allocate attribute is an allocation hint, that is, it is a recommendation to the memory system that, for performance reasons, the transaction is not allocated. However, the allocation of the transaction is not prohibited.

Write-Back Allocate

The required behavior for the Write-Back Allocate memory type is the same as for Write-Back No-allocate memory. However, in this case, the allocation hint is a recommendation to the memory system that, for performance reasons, the transaction is allocated.

2.7.5 Likely Shared

The LikelyShared attribute is a cache allocation hint. When asserted, this attribute indicates that the requested data is likely to be shared by other Request Nodes within the system. This acts as a hint to shared system level caches that the allocation of the cache line is recommended for performance reasons.

There is no required behavior associated with this transaction attribute.

The LikelyShared assertion requirements:

- Can be asserted in:
 - ReadClean
 - ReadNotSharedDirty
 - ReadShared
 - StashOnceUnique, StashOnceSepUnique
 - StashOnceShared, StashOnceSepShared
 - WriteUniquePtl
 - WriteUniqueFull
 - WriteUniqueZero
 - WriteUniquePtlStash
 - WriteUniqueFullStash
 - WriteBackFull
 - WriteCleanFull
 - WriteEvictFull
 - WriteEvictOrEvict
- Must not be asserted in any:
 - Combined Write transactions.
 - Dataless or Atomic transactions.
 - Other Read or Write transactions.
- Is not applicable in:
 - DVMOp or PCrdReturn transaction, and must be set to zero.
 - PrefetchTgt transaction and can take any value.

2.7.6 Snoop Attribute, SnpAttr

The SnpAttr field indicates if a transaction might require snooping.

Table 2-12 shows the SnpAttr field encodings.

Table 2-12 SnpAttr field encodings

SnpAttr	Snoop attribute
0	Non-snoopable
1	Snoopable

Table 2-13 shows the snoop attributes for the different transaction types. The following key is used:

Y	Yes, permitted
-	Not permitted
n/a	Not applicable

Table 2-13 Snoop attributes for the different transaction types

Transaction	Non-snoopable	Snoopable
ReadNoSnp, ReadNoSnpSep	Y	-
ReadOnce*, ReadClean, ReadShared, ReadNotSharedDirty, ReadUnique, ReadPreferUnique, MakeReadUnique	-	Y
CleanUnique, MakeUnique, StashOnce	-	Y
CleanShared, CleanSharedPersist*, CleanInvalid, MakeInvalid	Y	Y
Evict	-	Y
WriteNoSnp	Y	-
WriteBack, WriteClean, WriteEvictFull, WriteEvictOrEvict	-	Y
WriteUnique	-	Y
Atomic transactions	Y	Y
DVMOp	n/a ^a	n/a ^a
PrefetchTgt	n/a ^b	n/a ^b

- a. Not applicable, SnpAttr bit is used as a Domain Identifier in DVM transactions, see [DVM domain on page 8-329](#).
b. Not applicable, can take any value.

The SnpAttr field value in a CMO, in an Atomic, and in ReadNoSnp and ReadNoSnpSep from Home to Subordinate, must be set to zero, irrespective of the field value in the Request from the original Requester to Home. In Write and Combined Write transactions from Home to Subordinate, the bit position for the SnpAttr field is used for the DoDWT field. See [Home to Subordinate Write transactions on page 2-85](#) and [Home to Subordinate Combined Write and CMO transactions on page 2-87](#).

———— **Note** ————

For transactions that can take more than one value of SnpAttr, the value is typically determined from page table attributes.

2.7.7 Mismatched Memory attributes

It is permitted for two different agents to access the same location using mismatched MemAttr or SnpAttr values, at the same point in time.

Memory accesses from the different agents made with mismatched snoopability or cacheability attributes are considered software protocol errors. A software protocol error can cause loss of coherency and result in the corruption of data values. It is required that the system does not deadlock on a software protocol error, and that transactions always make forward progress. See [Software-based error on page 9-361](#).

A software protocol error for an access in one 4KB memory region must not cause data corruption in a different 4KB memory region.

For locations held in Normal memory, the use of appropriate software cache maintenance can be used to return memory locations to a defined state.

The use of mismatched memory attributes can result in an RN-F observing a Snoop transaction to the same address where the RN-F would use, or previously have used, Non-snoopable transactions to access. If an RN-F receives a Snoop to a location that it believes is Non-snoopable, it must not respond with data and instead send SnpResp_I. When mismatched attributes are used, there is no defined relationship between the Snoop transaction and the transaction that the RN-F has issued.

2.8 Data transfer

A data payload is included in Read transactions, Write transactions, Combined Write transactions, Atomic transactions, and Snoop responses with data. This section defines the data alignment rules and the data bytes that are accessed for different combinations of address, transaction size, and memory type.

In this section, unless explicitly stated otherwise, a reference to a Write transaction includes both the individual Write transaction and the corresponding Combined Write transaction.

2.8.1 Data size

The Size field in a packet is used, in combination with other fields, to determine the number of bytes transferred. [Table 2-14](#) shows the Size field value encodings. Snoop transactions do not include a Size field. All snoop data transfers are 64-byte.

Table 2-14 Size field value encodings

Size[2:0]	Bytes
0b000	1
0b001	2
0b010	4
0b011	8
0b100	16
0b101	32
0b110	64
0b111	Reserved

2.8.2 Bytes access in memory

The MemAttr[1] bit field determines if the memory type is Device or Normal. See [Memory Attributes on page 2-134](#). The bytes that are accessed are determined by the memory type as follows:

Normal memory

Transactions with a Normal memory type access the number of bytes defined by the Size field. Data access is from the Aligned_Address, that is, the transaction address rounded down to the nearest Size boundary and ends at the byte before the next Size boundary.

This is calculated as:

Start_Address = Addr field value.

Number_Bytes = $2^{\text{Size field value}}$.

INT(x) = Rounded down integer value of x.

Aligned_Address = (INT(Start_Address / Number_Bytes)) x Number_Bytes.

The bytes accessed are from (Aligned_Address) to (Aligned_Address + Number_Bytes) - 1.

Device memory

Transactions with a Device memory type access the number of bytes from the transaction address up to the byte before the next Size boundary.

The bytes accessed are from (Start_Address) to (Aligned_Address + Number_Bytes) - 1.

For Write transactions to Device locations, byte enables must only be asserted for the bytes that are accessed. See [Byte Enables on page 2-143](#).

2.8.3 Byte Enables

Byte Enables, also referred to as BE, are used alongside Write transactions and Snoop responses with Data.

In the following sections, unless explicitly stated otherwise, a reference to a Write transaction includes both the individual Write transaction and the corresponding Combined Write transaction.

In WriteData and Snoop responses, a data byte enable value of zero must set the associated data byte value to zero.

Write transactions

For all Write transactions, byte enables that are not within the data window, specified by Addr and Size, must be deasserted.

An asserted byte enable in Write transactions indicates that the associated data byte is valid and must be updated in memory or cache. A deasserted byte enable indicates that the associated data byte is not valid and must not be updated in memory or cache.

A Requester must deassert all BE values in CopyBackWrData_I and WriteDataCancel packets.

During data transfers in the following write transactions:

- All byte enables must be asserted, except when write data is a CopyBackWrData_I or WriteDataCancel packet:
 - WriteNoSnpFull
 - WriteBackFull
 - WriteCleanFull
 - WriteEvictFull
 - WriteUniqueFull
 - WriteUniqueFullStash
- Any combination of byte enables are permitted, including asserting all and asserting none:
 - WriteBackPtl
 - WriteUniquePtl
 - WriteUniquePtlStash

For a WriteNoSnpPtl transaction, the following rules apply:

- For a transaction to Normal memory, any combination of byte enables can be asserted during the data transfers. This includes asserting all and asserting none.
- For a transaction to Device memory, byte enables must only be asserted for bytes at or above the address specified in the transaction. Any combination of byte enables can be asserted that meets this requirement. This includes asserting all and asserting none.

Atomic transactions

For Atomic transactions, all byte enables within the data window must be asserted.

For Atomic transactions, byte enables that are not within the data window, as specified below by Addr and Size, must be deasserted:

- If Addr is aligned to Size, the Data window is [Addr: (Addr+Size-1)].
- If Addr is not aligned to Size, the Data window is [(Addr-Size/2): (Addr+Size/2-1)].

Snoop transactions

For Snoop responses with data that use the SnpRespData opcode, all byte enables must be asserted.

For Snoop responses with data that use the SnpRespDataPtl opcode, any combination of byte enables can be asserted alongside the data transfers. This includes asserting all and asserting none.

2.8.4 Data packetization

For each transaction that involves data, the data bytes can be transferred in multiple packets.

The number of packets required is determined by:

- Number of bytes
- Data bus width

The number of bytes transferred in each packet is determined by:

- Data bus width

This specification supports the following data bus widths:

- 128-bit
- 256-bit
- 512-bit

The *Data Identifier* (DataID) and *Critical Chunk Identifier* (CCID) fields are used to identify data packets within a transaction.

A transaction size of up to 16-byte is always contained in a single packet. The DataID can be calculated for each packet based on the data bus width:

- 128-bit: bits [5:4] of the effective memory address of any byte in the packet
- 256-bit: bit [5] of the effective memory address of any byte in the packet, concatenated with 0b0
- 512-bit: always 0b00

For different data bus widths, [Table 2-15](#) shows the relationship between the DataID field and the bytes that are contained within the packet.

Table 2-15 DataID and the bytes within a packet for different data widths

DataID	Data Width		
	128-bit	256-bit	512-bit
0b00	Data[127:0]	Data[255:0]	Data[511:0]
0b01	Data[255:128]	Reserved	Reserved
0b10	Data[383:256]	Data[511:256]	Reserved
0b11	Data[511:384]	Reserved	Reserved

Within a data packet, all bytes are located at their natural byte positions. This is true even if fewer data bytes are transferred than the width of the data bus.

The number of data packets used for transactions to Device memory is independent of the address of the transaction. The number of data packets required is determined only by the Size field and the data bus width.

———— Note ————

For some transactions to Device memory, it can be determined from the address at the start of the transaction that some data packets will not contain valid data and are redundant. However, it is required that these data packets are transferred.

When a DAT message is split into multiple packets:

- The fields that must be consistent are:
 - TgtID
 - SrcID

- TxnID
- HomeNID
- Opcode
- Resp
- FwdState
- DataPull
- DataSource
- CBusy
- DBID
- CCID
- TagOp
- The field tags that are expected to be consistent, but can vary, are:
 - QoS
 - RespErr
 - TraceTag
- The fields that are expected to vary are:
 - Data
 - DataID
 - Tag
 - RSVDC
 - BE
 - DataCheck
 - Poison

2.8.5 Size, Address and Data alignment in Atomic transactions

This section describes the data size and alignment requirements for Atomic transactions. It contains the following sub-sections:

- [Size](#)
- [Address and Data alignment](#)
- [Endianness on page 2-147](#)

Size

The Size field of the packet specifies the total data size of the Atomic transaction.

For the AtomicCompare transaction, the data size is the sum of the Compare and Swap data values.

[Table 2-16](#) shows the permitted data sizes, and the relationship between inbound and outbound valid data size for each Atomic transaction type. The size of the data value returned in response to an AtomicCompare transaction is half the number of bytes specified in the Size field in the associated Request packet.

Table 2-16 Atomic transaction outbound and inbound data sizes

Atomic transaction	Outbound (bytes)	Inbound
AtomicStore	1, 2, 4, or 8	-
AtomicLoad	1, 2, 4, or 8	Same as outbound
AtomicSwap	1, 2, 4, or 8	Same as outbound
AtomicCompare	2, 4, 8, 16, or 32	Half size of outbound

Address and Data alignment

In the AtomicStore, AtomicLoad, and AtomicSwap transactions:

- The byte address is aligned to the outbound data size.
- The position of data bytes in the Data packet matches the endianness of the operation, as specified in the Endian field of the request.
- The big-endian data is byte invariant.

The write data associated with an AtomicCompare transaction is provided as if it were for a transaction that is aligned to the outbound data size.

In the AtomicCompare transaction:

- The byte address must be aligned in the Data packet to the inbound data size, which is equivalent to half the outbound data size.

The two data values in an AtomicCompare transaction are placed in the data field in the following manner:

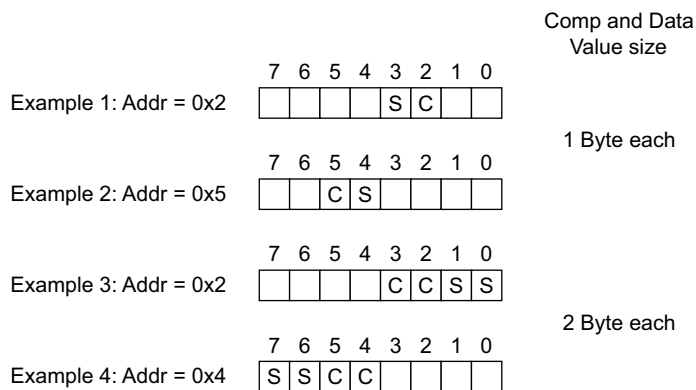

- The Compare and Swap data values are concatenated and the resulting data payload is aligned in the Data packet to the outbound data size.
- The Compare data is always at the addressed byte location.
- The Swap data is always in the remaining half of the valid data.

For any given Compare data address, the Swap data address can be determined by inverting bit[n] in the Compare data address where:

- $n = \log_2(\text{Compare data size in bytes})$

Alignment example

Figure 2-36 shows examples of data placement with different addresses and different Data size.

Only 8 bytes of the 16 byte data packet are shown

Figure 2-36 Data value packing for AtomicCompare transaction

In Figure 2-36, Example 1 shows the addressed byte location is 0x2 and the total size of data is two bytes. In this case, the Compare and Swap data must be placed in an address location aligned to a 2-byte boundary that includes the addressed location, that is, addresses 0x2 to 0x3. Compare data is placed in location 0x2 and Swap data is placed in location 0x3.

———— **Note** ————

The address of the Swap data can be determined by inverting bit[0] of the Compare data address. Bit[0] is inverted because the size of the Compare data and the size of the Swap data is 1 byte.

In Figure 2-36, Example 3 shows the addressed location is 0x2 and the total size of data is four bytes. In this case, the Compare and Swap data must be placed in an address location aligned to a 4 byte boundary that includes the addressed location, that is, addresses 0x0 to 0x3. Compare data is placed in location 0x2 and Swap data is placed in location 0x0.

———— **Note** ————

The address of the Swap data can be determined by inverting bit[1] of the Compare data address. Bit[1] is inverted because the size of the Compare data and the size of the Swap data is two bytes.

Endianness

The data on which an atomic operation executes can be in either little-endian or big-endian format. For arithmetic operations, such as ADD, MAX, and MIN, the component performing the operation needs to know the format of the data.

The endian format of the data is defined by the Endian bit in the Atomic transaction Request packet. See [Endian](#) on page 13-440.

2.8.6 Critical Chunk Identifier

The CCID field is used to identify the data bytes that are the most critical in the transaction request.

The CCID field must match the value of Addr[5:4] of the original request. Transactions which contain multiple data packets must use the same CCID value for all data packets.

When read data or write data is reordered by the interconnect, the CCID field permits quick identification of the most critical bytes within a transaction by comparing the CCID value with the DataID value. When the two values match, the data bytes being transferred are the critical bytes.

The bits to match is dependent on the data bus width:

- For a data bus width of 128 bits, the CCID and DataID bits must match for the critical chunk.
- For a data bus width of 256 bits, only the most significant CCID and DataID bits must match for the critical chunk.

2.8.7 Critical chunk first wrap order

The Sender of Data is permitted, but not required, to send individual Data packets of a transaction in critical chunk first wrap order.

The interface property, CCF_Wrap_Order, defines the capabilities of a Sender, and the guarantees provided by the Receiver:

- CCF_Wrap_Order at the Sender:
 - True** The Sender signals that it is capable of sending Data packets in critical chunk first wrap order.
 - False** The Sender signals that it is not capable of sending Data packets in critical chunk first wrap order.
- CCF_Wrap_Order at the interconnect:
 - True** The interconnect guarantees that it will maintain the Data packets of a transaction in the order they are received.
 - False** The interconnect signals that it does not guarantee it can maintain the Data packets of a transaction in the order they are received.
- CCF_Wrap_Order at the Receiver that is not an interconnect:
 - True** The Receiver requires the Data packets to be received in critical chunk first wrap order.
 - False** The Receiver does not require the Data packets to be received in critical chunk first wrap order.

If some components in the system do not support sending Data packets in critical chunk first wrap order, the receiver of Data must not rely on Data being received in critical chunk first wrap order.

———— **Note** ————

At design time, the CCF_Wrap_Order parameter can help a component to identify if Data packets need to be sent in critical chunk first wrap order. For example, if the component knows that it is connected to an out-of-order interconnect, then it might be able to simplify its Data packet path by not returning the Data packets in critical chunk first wrap order.

If the interconnect has CCF_Wrap_Order set to True, a component interfacing to that interconnect can send data packets in critical chunk first wrap order, if capable. The Receiver can then make use of possible latency optimization, due to receiving the critical chunk first.

2.8.8 Data Beat ordering

The reordering of data packets within a transaction is permitted when passing across an interconnect. However, the original source of data packets is permitted, but not required, to provide the packets in a critical chunk first, wrap order. See [Critical chunk first wrap order on page 2-148](#).

Note

Critical chunk first wrap order ensures that interfacing to protocols that do not support data reordering, such as AXI, can be done in the most efficient manner when an ordered interconnect is used.

Wrap order is defined as follows:

$\text{Start_Address} = \text{Addr}$

$\text{Number_Bytes} = 2^{\text{Size}}$

$\text{INT}(x) = \text{Rounded down integer value of } x$

$\text{Aligned_Address} = (\text{INT}(\text{Start_Address} / \text{Number_Bytes})) \times \text{Number_Bytes}$

$\text{Lower_Wrap_Boundary} = \text{Aligned_Address}$

$\text{Upper_Wrap_Boundary} = \text{Aligned_Address} + \text{Number_Bytes} - 1$

To maintain wrap order, the order must be:

1. The first data packet must correspond to the data bytes specified by the Start_Address of the transaction.
2. Subsequent packets must correspond to incrementing byte addresses up to the Upper_Wrap_Boundary.
3. Subsequent packets must correspond to the Lower_Wrap_Boundary.
4. Subsequent packets must correspond to incrementing byte addresses up to the Start_Address.

Note

Some of the steps to maintain wrap order might overlap and not be required if the required bytes are included in a previous step.

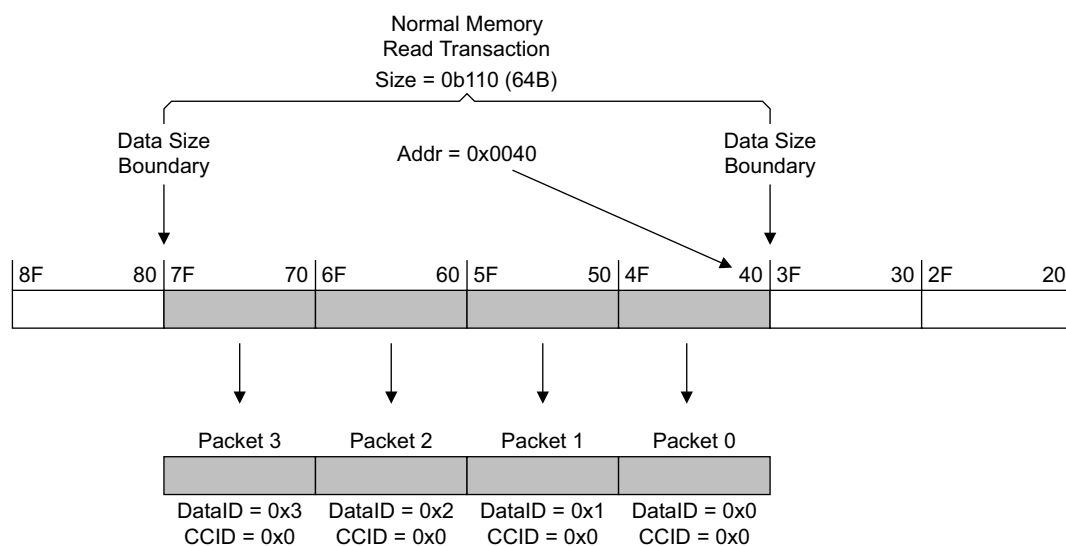

2.8.9 Data transfer examples

This section gives a number of examples of the data transfer requirements defined in this specification.

In most of the examples, the size of the transaction is 64 bytes and the data bus width is 128 bits. This requires 4 data packets for each transaction.

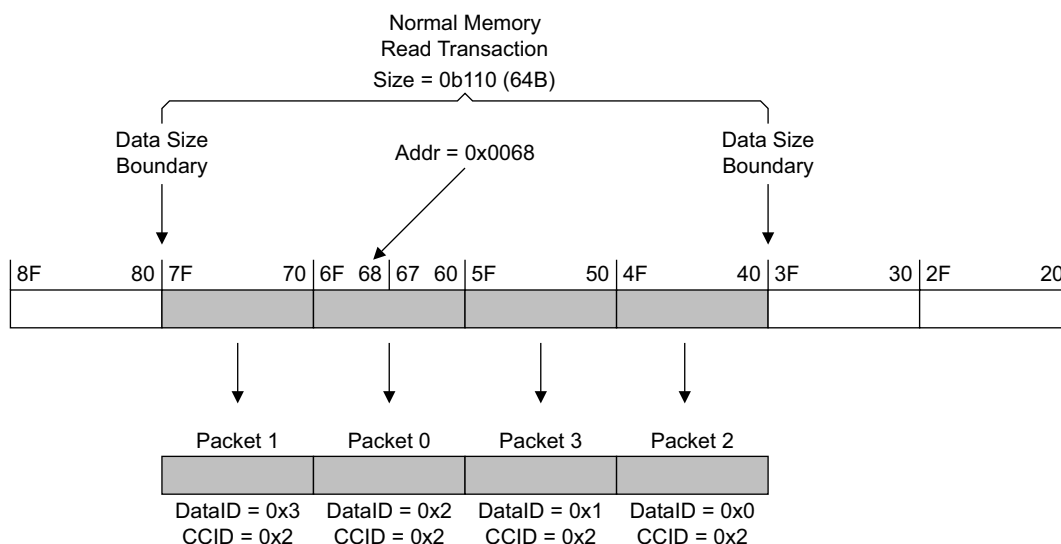

In the following examples, the accompanying text highlights some interesting aspects. It is not intended to describe all aspects of the example.

Example 2-1 Normal memory 64-byte Read transaction from an aligned address

- The order of the data packets, as indicated by Packet 0, Packet 1, Packet 2, and Packet 3, is such that they follow wrap order.
- The DataID changes for each packet, while the CCID field remains constant.
- The packet containing the data bytes specified by the address of the transaction has the same value for the CCID and DataID fields.

Example 2-2 Normal memory 64-byte Read transaction from an unaligned address

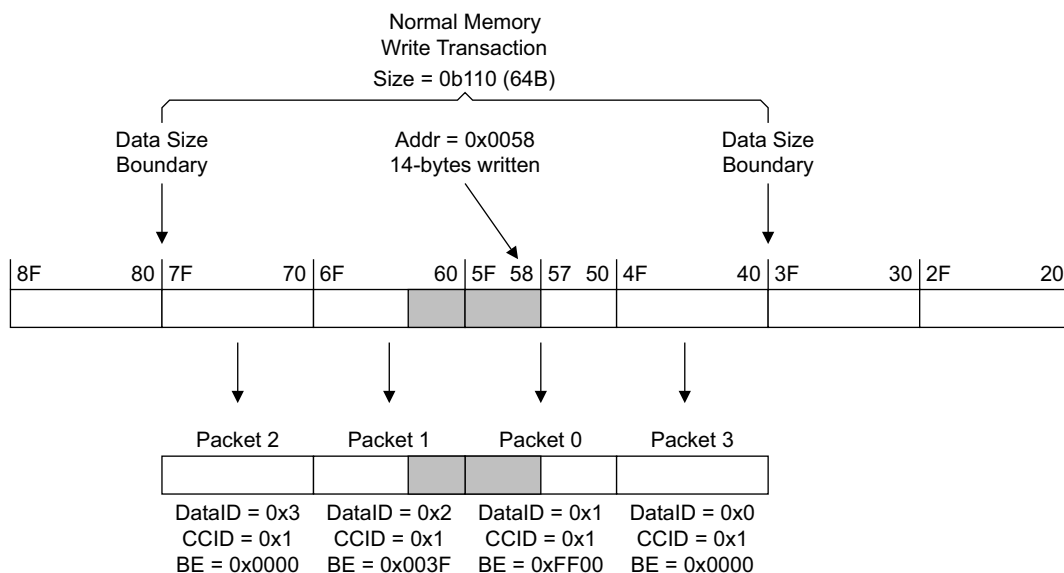

- The order of the data packets, as indicated by Packet 0, Packet 1, Packet 2, and Packet 3, is such that they follow wrap order.
- The DataID changes for each packet, while the CCID field remains constant.
- The packet containing the data bytes specified by the address of the transaction has the same value for the CCID and DataID fields.

Example 2-3 Normal memory 32-byte Read transaction from an unaligned address

- The size of the transaction is 32-byte and the data bus width is 128-bit, resulting in 2 data packets.
- The order of the data packets, as indicated by Packet 0 and Packet 1, is such that they follow wrap order.

Example 2-4 Normal memory 14-byte consecutive write transaction from an unaligned address

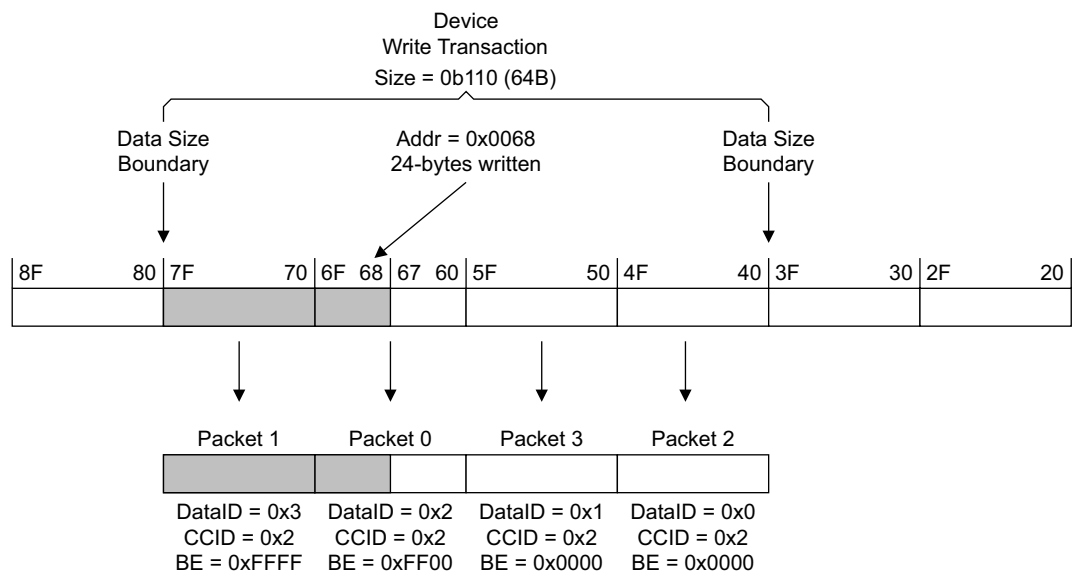

- The order of the data packets, as indicated by Packet 0, Packet 1, Packet 2, and Packet 3, is such that they follow wrap order.
- The DataID changes for each packet, while the CCID field remains constant.
- The packet containing the data bytes specified by the address of the transaction has the same value for the CCID and DataID fields.
- Fourteen consecutive bytes in memory are written, as indicated by the byte enables. However, other combinations of byte enables are permitted. See [Byte Enables](#) on page 2-143.

Example 2-5 Device Read transaction from an unaligned address

- The shaded area indicates the valid bytes in the transaction. The valid bytes extend from the transaction address up to the next Size boundary.
- The transaction includes the transfer of a packet that contains no valid data.

Example 2-6 Device write transaction to an unaligned address

- Byte enables are only permitted to be asserted for the bytes from the transaction address up to the next Size boundary. It is not required that all byte enables meeting this criteria are asserted.
- Byte enables for bytes below the start address must not be asserted.

2.9 Request Retry

This specification provides a Request Retry mechanism that ensures when a request reaches a Completer it is either accepted or given a RetryAck response to prevent blocking of the REQ channel.

Request Retry is not applicable to the PrefetchTgt transaction. The PrefetchTgt transaction cannot be retried because there is no response associated with this request.

A Requester is required to hold all the details of the request until it receives a response indicating that the request has either been accepted or must be sent again at a later point in time. To meet this requirement, except for PrefetchTgt, the AllowRetry field must be asserted the first time a transaction is sent.

A Completer that is receiving requests is able to give a RetryAck response to a request that it is not able to accept. Typically, it will not be able to accept a request when it has limited resources and insufficient storage to hold the current request until some earlier transactions have completed.

When a Completer gives a RetryAck response, it is responsible for recording where the request came from, as determined by the SrcID of the request. The Completer is also responsible for determining and recording the type of *Protocol Credit* (P-Credit) required to process the request. The PCrdType field in the RetryAck encodes the type of P-Credit that will be granted by the Completer. When required resources become available, at a later point in time, the Completer must then send a P-Credit to the Requester, using a PCrdGrant response. The PCrdGrant response indicates to the Requester that the transaction can be retried.

———— Note ————

There is no explicit mechanism to request a credit. A transaction that is given a RetryAck response implicitly requests a credit.

It is possible that responses can be reordered so PCrdGrant is received by the Requester before the RetryAck response for the transaction is received. In this case, the Requester must record the credit it has received, including the credit type, so that it can assign the credit appropriately when it does receive the RetryAck response.

———— Note ————

The delay between a RetryAck and PCrdGrant response will typically be much longer than any delay caused by interconnect reordering. PCrdGrant is expected to rarely be reordered with respect to RetryAck.

When the Requester receives a credit, it can then resend the request with an indication that it has been allocated a credit. This is done by deasserting the AllowRetry field. This second attempt to carry out the transaction is guaranteed to be accepted.

The transaction that is resent must have the same field values as the original request, except when the field is inapplicable or is one of the following:

- QoS
- TgtID, see [Target ID determination for Request messages on page 3-162](#)
- TxnID
- ReturnTxnID for ReadNoSnp and ReadNoSnpSep from the Home Node to the Subordinate Node
- SLCTRepHint
- AllowRetry, which must be deasserted
- PCrdType, which must be set to the value in the Retry response for the original transaction
- TraceTag
- RSVDC

When the Requester receives a RetryAck response for a CopyBack Write request whose data is invalidated by a snoop, the Requester can either:

- Drop the Write request and return the received credit.
- Send the Write request with AllowRetry set to zero, knowing that the subsequent data response will be CopyBackWrData_I.

There is no fixed relationship between credits and particular transactions. If a Requester has received multiple RetryAck responses for different transactions and then receives a credit, there is no fixed credit allocation. The Requester is free to choose the most appropriate transaction from the list of transactions that receives a RetryAck response with that particular Protocol Credit Type.

The Retry mechanism supports up to 16 different credit types. This lets the Completer use different credit types for different resources. For example, a Completer might use one credit type for the resources associated with Read transactions, and another credit type for Write transactions. Using different credit types gives the Completer the ability to efficiently manage its resources by controlling which of the retried requests can be sent again.

The transaction must only be retried by the Requester when a PCrdGrant is received with the correct PCrdType.

———— Note ————

If a Completer is only using one credit type, it is recommended that the PCrdType value of 0b0000 is used. See [PCrdType on page 2-156](#).

A Completer that is giving RetryAck responses must be able to record all the RetryAck responses that it has given to ensure it can correctly distribute credits. If the Completer is using more than one credit type, the RetryAck responses that have been given for each credit type must be recorded.

A Requester must limit the transactions it issues so that the Completer is never required to track more than 1024 transactions that require a PCrdGrant response. This is achieved by limiting the maximum number of outstanding transactions to 1024 for each Requester.

A transaction is outstanding from the cycle that the request is first issued until either:

- The transaction is fully completed, as determined by the return of all the following responses that are expected for the transaction:
 - ReadReceipt
 - CompData
 - RespSepData
 - DataSepResp
 - DBIDResp*
 - Comp, CompCMO, CompPersist, and CompStashDone
 - CompDBIDResp
- It receives RetryAck and PCrdGrant and is either:
 - Retried using a credit of the appropriate PCrdType and then is fully completed as determined by the return of all responses.
 - Canceled and returns the received credit using the PCrdReturn message.

A Requester can reuse the TxnID value used by a request either:

- As soon as it receives a RetryAck response for that request.
- As soon as it receives all the required responses for that request if the received responses are Non-RetryAck responses.

Each transaction request includes a QoS value which can be used by the Completer to influence the allocation of credits as resources become available. See [Chapter 10 Quality of Service](#) for further details.

2.9.1 Credit Return

It is possible for a Requester to be given more credits than it requires.

This specification does not define when this can occur, but two typical scenarios are:

- A transaction is canceled between the first attempt and the point at which it can be resent with P-Credit.
- A transaction is requested multiple times with increasing QoS values. However, only a single completion of the transaction is required.

Note

If a Requester makes a second request before the first request has been given a RetryAck response, it must be acceptable for both transactions to occur. However, as an example, this behavior would typically not be acceptable for accesses to a peripheral device.

A Requester returns a credit by the use of the PCrdReturn transaction. This is effectively a No Operation transaction that uses the credit that is not required. This transaction is used to inform the Completer that the allocated resources are no longer required for the given PCrdType.

Any credits that are not required must be returned in a timely manner.

Note

Any unused pre-allocated credit must be returned to avoid components holding on to credits in expectation of using them later. Such behavior is likely to result in an inefficient use of resources and to make analysis of the system performance difficult.

2.9.2 Transaction Retry mechanism

The following sections describe the Request transaction fields used by the Retry mechanism.

The transaction retry mechanism is not applicable to the PrefetchTgt transaction.

AllowRetry

The AllowRetry field indicates if the Request transaction can be given a RetryAck response. See [Table 13-26 on page 13-440](#) for the AllowRetry value encodings. The AllowRetry field must be asserted the first time a transaction is sent.

The AllowRetry field must be deasserted when either:

- The transaction is using a pre-allocated P-Credit.
- The transaction is PrefetchTgt.

PCrdType

The PCrdType field indicates the credit type associated with the request and is determined as follows:

- For a Request transaction:
 - If the AllowRetry field is asserted, the PCrdType field must be set to 0b0000.
 - If the AllowRetry field is deasserted, the PCrdType field must be set to the value that was returned in the RetryAck response from the Completer when the transaction was first attempted.
- A PCrdReturn transaction must have the credit type set to the value of the credit type that is being returned. See [Protocol Credit Type, PCrdType on page 13-442](#) for the PCrdType value encodings.
- For destinations that have a single credit class, or do not implement credit type classification, it is recommended that the PCrdType field is set to 0b0000.

Note

The value a Completer assigns to PCrdType is IMPLEMENTATION DEFINED.

The Completer must implement a starvation prevention mechanism to ensure that all transactions, irrespective of QoS value or credit type required, will eventually make forward progress, even if over a significantly long time period. This is done by ensuring that credits are eventually given to every transaction that has received a RetryAck response. See [Chapter 10 Quality of Service](#) for more details on the distribution of credits for the purposes of QoS.

2.9.3 Transaction Retry flow

Figure 2-37 shows a typical Transaction Retry flow.

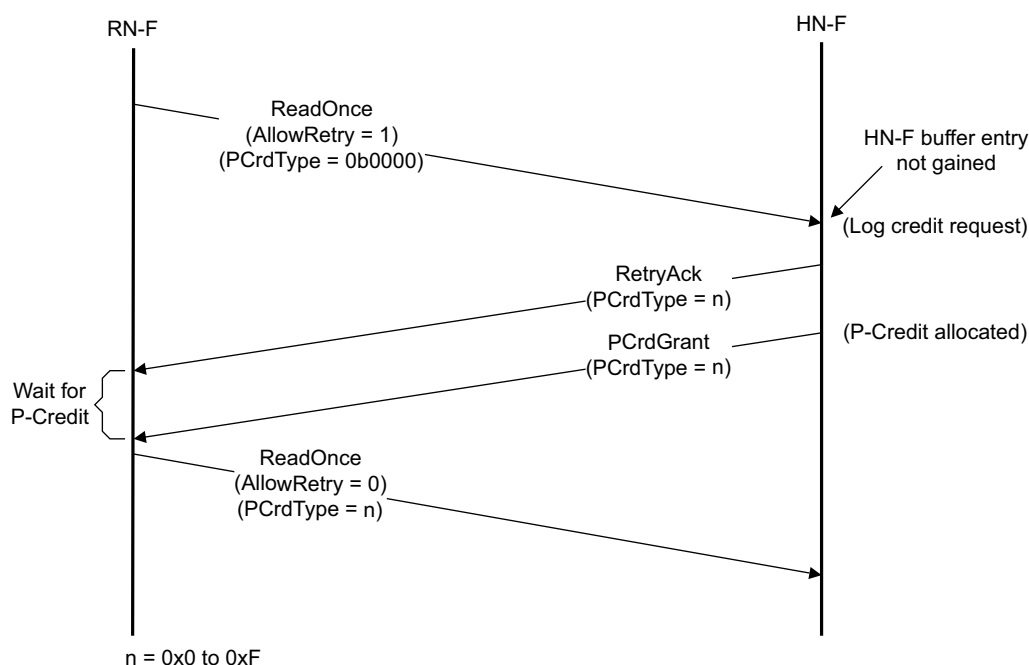

Figure 2-37 Transaction Retry flow

The steps in Figure 2-37 include:

1. The RN-F sends a **ReadOnce** request to the HN-F
 - This is done without a credit, so **AllowRetry** is asserted. This means **PCrdType** must be set to **0b0000**.
2. The HN-F receives the request and sends a **RetryAck** response because the request is not able to gain buffer entry at the HN-F.
 - The request is logged and a **PCrdType** is determined at the HN-F.
3. The HN-F sends a P-Credit, using the **PCrdGrant** response, when it has allocated resource for the transaction.
 - The **PCrdGrant** includes the **PCrdType** allocated for the original request.
4. The RN-F re-sends the **ReadOnce** transaction with **AllowRetry** deasserted.
 - The request uses the P-Credit and sets the **PCrdType** field to the value allocated for the original request.

It is permitted, but not expected, for a Completer to send a **PCrdGrant** before it has sent the associated **RetryAck** response.

Note

The Requester might receive **PCrdGrant** before **RetryAck**.

The transaction must not be resent until both a **RetryAck** response and an appropriate P-Credit is received for the transaction.

Chapter 3

Network Layer

This chapter describes the network layer that is responsible for determining the node ID of a destination node. It contains the following sections:

- *System Address Map, SAM* on page 3-160
- *Node ID* on page 3-161
- *Target ID determination* on page 3-162
- *Network layer flow examples* on page 3-165

3.1 System Address Map, SAM

Requesters must have a *System Address Map* (SAM) to determine the target ID of a request. Requesters might be Request Nodes or Home Nodes. The scope of the SAM might be as simple as providing a fixed node ID value to all the outgoing requests.

The exact format and structure of the SAM is IMPLEMENTATION DEFINED and is outside the scope of this specification.

The SAM must provide a complete decode of the entire address space. It is recommended that any address that does not correspond to a physical component is sent to an agent that can provide an appropriate error response.

3.2 Node ID

Each component connected to a Port on the interconnect is assigned a node ID that is used to identify the source and destination of packets communicated over the interconnect. A Port can be assigned multiple node IDs. A node ID value can be assigned only to a single Port.

This specification supports a variable NodeID field width of 7 bits to 11 bits.

The width can be configured to any fixed value within this range for a given implementation and this value must be consistent across all NodeID fields.

Defining and assigning a node ID for each node in a system is IMPLEMENTATION DEFINED and is outside the scope of this specification.

3.3 Target ID determination

This section describes how the target ID is determined for the different message types. It contains the following sections:

- [Target ID determination for Request messages](#)
- [Target ID determination for Response messages on page 3-163](#)
- [Target ID determination for snoop request messages on page 3-164](#)

3.3.1 Target ID determination for Request messages

For mapping of target ID in requests from the Request Node, it is required that the SAM logic to be present in the Request Node or in the interconnect. In the case of the interconnect, it might remap the target ID in the Request packet provided by the Request Node.

The target ID of a Request message is determined in the following manner using the SAM logic.

Except for PCrdReturn:

- If the request does not use a pre-allocated credit, the target ID is determined by:
 - Opcode for DVMOOp.
 - Address to node ID mapping for all other requests.
PrefetchTgt uses a different Address to node ID mapper than other requests. Two requests from a Request Node to the same Address, where one is a PrefetchTgt, target different nodes. PrefetchTgt always targets a Subordinate Node. All other requests from a Request Node that use an Address to node ID mapper target a Home Node.
- If the request uses pre-allocated credit, the target ID of the Request must be obtained from either the source ID of the RetryAck, provided as a response to the original Request message, or the target ID of the original request.

For PCrdReturn:

- The target ID provided by the Request Node must match the source ID included in the prior PCrdGrant which provided the credit being returned.

A Request Node must expect the interconnect to remap the target ID of a request.

For transactions from a Request Node, except for PrefetchTgt which is targeted to an SN-F, it is expected a Snoopable transaction to be targeted to HN-F and a Non-snoopable transaction to target HN-I or HN-F. It is legal for a Snoopable transaction to be targeted at an HN-I. This might occur, for example, due to a software programming error. In this case, the HN-I is required to respond to the transaction in a protocol-compliant manner, but coherency is not guaranteed.

A Home Node might also use address map logic to determine the target Subordinate Node ID for each request.

3.3.2 Target ID determination for Response messages

Response packets are issued as a result of a received message. The target ID in Response packets must match either the SrcID, HomeNID, ReturnNID, or FwdNID in the received message that resulted in the response being sent.

Table 3-1 shows the source of the Response packet target ID for each Response message type and the field in the received message that determines the target ID.

Table 3-1 Source of response packet target ID

Response message	Target ID obtained from		
	At the HN	At the SN	At the RN
RetryAck	Request.SrcID	Request.SrcID	-
PCrdGrant	Request.SrcID	Request.SrcID	-
ReadReceipt	Request.SrcID	Request.SrcID	-
RespSepData	Request.SrcID or SnpResp*.SrcID ^a	-	-
Comp	Request.SrcID	Request.SrcID	-
CompCMO	Request.SrcID	Request.SrcID	-
DataSepResp	Request.SrcID or SnpResp*.SrcID ^a	Request.ReturnNID	-
CompData	Request.SrcID or SnpResp*.SrcID ^a	Request.ReturnNID	Snoop.FwdNID
CompAck (reads)	-	-	Comp.SrcID or RespSepData.SrcID or CompData.HomeNID
CompAck (writes)	-	-	Comp.SrcID or DBIDResp*.SrcID or CompDBIDResp.SrcID
CompDBIDResp	Request.SrcID	Request.SrcID ^b	
DBIDResp	Request.SrcID	If Request.DoDWT == 0 then: Request.SrcID or If Request DoDWT == 1 then: Request.ReturnNID	-
DBIDRespOrd	Request.SrcID	-	-
WriteData	-	-	DBIDResp*.SrcID or CompDBIDResp.SrcID
NCBWrDataCompAck	-	-	Comp.SrcID or DBIDResp*.SrcID or CompDBIDResp.SrcID
Persist	Request.SrcID	Request.ReturnNID	-
CompPersist	Request.SrcID	Request.SrcID ^b	-
StashDone	Request.SrcID	-	-

Table 3-1 Source of response packet target ID (continued)

Response message	Target ID obtained from		
	At the HN	At the SN	At the RN
CompStashDone	Request.SrcID	-	-
TagMatch	Request.SrcID	Request.ReturnNID	-
SnpResp* ^c	-	-	Snoop.SrcID

- a. For Data Pull requests where Snoop response can be SnpResp or SnpRespData or SnpRespDataPtl.
- b. This response is only permitted when Request.SrcID = Request.ReturnNID, including when Request.DoDWT = 1.
- c. SnpResp, SnpRespData, SnpRespDataPtl, SnpRespFwdded, and SnpRespDataFwdded.

3.3.3 Target ID determination for snoop request messages

A snoop request does not include a target ID. The protocol does not define an architectural mechanism to address and send a Snoop request to a target. It is expected that this mechanism will be IMPLEMENTATION DEFINED and is outside the scope of this specification.

3.4 Network layer flow examples

This section shows transaction flows at the network layer. It contains the following sections:

- [Simple flow](#)
- [Flow with interconnect-based SAM on page 3-166](#)
- [Flow with interconnect-based SAM and Retry request on page 3-167](#)

The following figures contain the term ‘Dec’ that represents the Decode.

3.4.1 Simple flow

Figure 3-1 is an example of a simple transaction flow and shows how the TgtID is determined for the requests and responses.

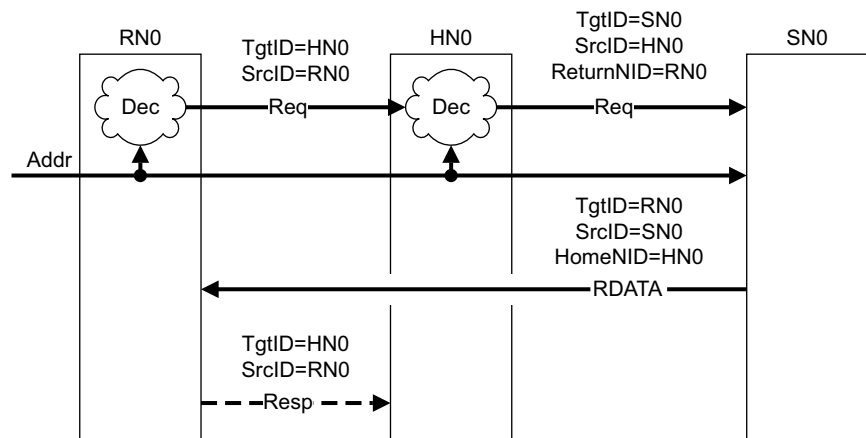

Figure 3-1 TgtID assignment without remapping

The steps for TgtID assignment without remapping in Figure 3-1 are:

1. RN0 sends a request with TgtID of HN0 using the SAM internal to RN0.
 - The interconnect does not remap the node ID.
2. HN0 looks up an internal SAM to determine the target Subordinate Node.
3. SN0 receives the request and sends a data response.
 - The data response packet has the TgtID derived from the requests ReturnNID.
4. RN0 receives the data response from SN0.
5. RN0 sends, if necessary, a CompAck response with TgtID of HN0 derived from the HomeNID in the data response packet to complete the transaction.

3.4.2 Flow with interconnect-based SAM

Figure 3-2 shows a case where remapping of the TgtID occurs in the interconnect.

Note

Only the TgtID of the request from the Request Node is remapped. The TgtID in all other packets in the transaction flow is determined in a similar manner to [Simple flow on page 3-165](#).

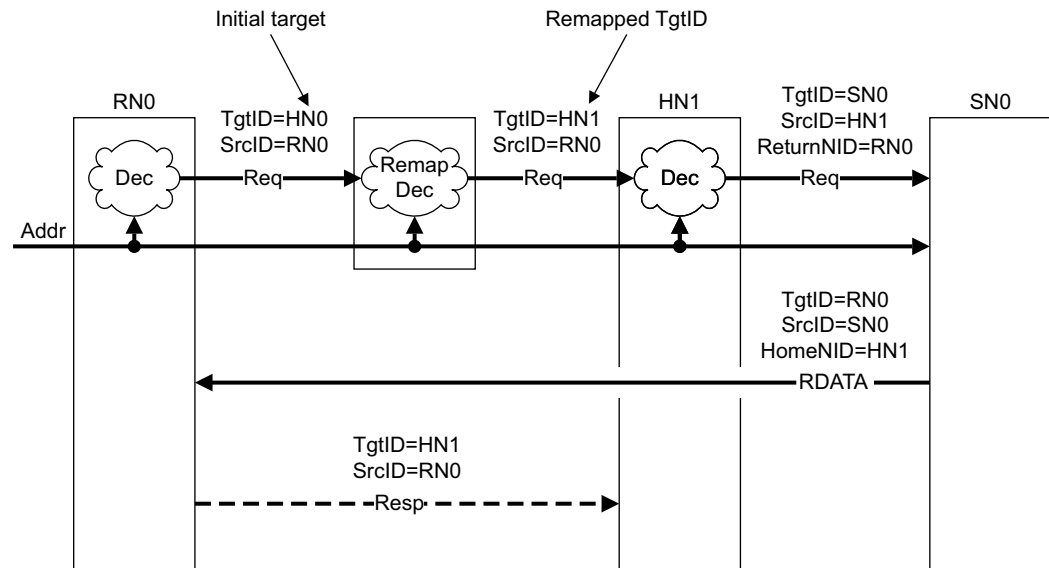

Figure 3-2 TgtID assignment with remapping logic

The steps for TgtID assignment with remapping logic in Figure 3-2 are as follows:

1. RN0 sends a Request with TgtID of HN0 using the SAM internal to RN0.
2. The interconnect remaps the request TgtID from HN0 to HN1. The SrcID remains set to the original requester, RN0.
3. HN1 looks up an internal SAM to determine the target Subordinate Node. The ReturnNID is set to match the original Requester, RN0.
4. SN0 receives the request and sends a data response.
 - The data response packet has the TgtID derived from the requests ReturnNID, with HomeNID set to match the remapped Home Node.
5. RN0 receives the data response from SN0.
6. If necessary, the RN0 sends a CompAck response with TgtID of HN1 derived from the HomeNID in the data response packet to complete the transaction.

3.4.3 Flow with interconnect-based SAM and Retry request

Figure 3-3 shows a case of a request getting retried.

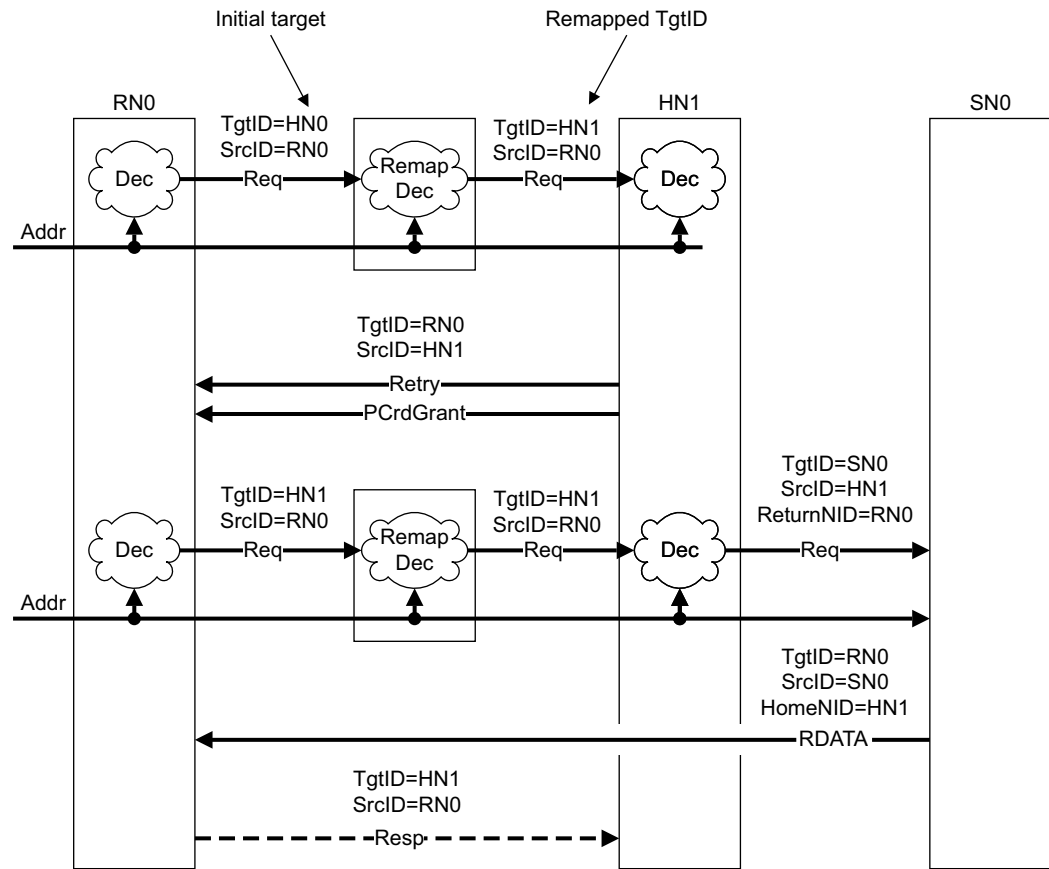

Figure 3-3 Remapping of TgtID and retried request

The steps to remap TgtID and retry the request in Figure 3-3 are as follows:

1. The interconnect remaps the TgtID provided by RN0 to HN1.
2. The request receives a RetryAck response.
 - The RetryAck and PCrdGrant responses get the TgtID information from the SrcID in the received request.
3. RN0 resends the request once both RetryAck and PCrdGrant responses are received.
 - The TgtID in the retried request is the same as the SrcID in the received RetryAck or the TgtID in the original request. The TgtID must pass through the remapping logic again.
4. The packets in the rest of the transaction flow get the TgtID in a similar manner to *Flow with interconnect-based SAM* on page 3-166.

Chapter 4

Coherence Protocol

This chapter describes the coherence protocol and contains the following sections:

- *Cache line states* on page 4-170
- *Request types* on page 4-172
- *Snoop request types* on page 4-201
- *Request transactions and corresponding Snoop requests* on page 4-204
- *Response types* on page 4-208
- *Silent cache state transitions* on page 4-220
- *Cache state transitions at a Requester* on page 4-221
- *Cache state transitions at a Snoopee* on page 4-232
- *Returning Data with Snoop response* on page 4-251
- *Do not transition to SD* on page 4-252
- *Hazard conditions* on page 4-253

4.1 Cache line states

The action required when a protocol node accesses a cache line is determined by the cache line state. The protocol defines the following cache line states:

I Invalid:

- The cache line is not present in the cache.

UC Unique Clean:

- The cache line is present only in this cache.
- The cache line has not been modified with respect to memory.
- The cache line can be modified without notifying other caches.
- In response to a snoop that requests data, the cache line is permitted, but not required, to be:
 - Returned to Home when requested.
 - Forwarded directly to the Requester when instructed by the snoop.

UCE Unique Clean Empty:

- The cache line is present only in this cache.
- The cache line is in a unique state but none of the data bytes are valid.
- The cache line can be modified without notifying other caches.
- In response to a snoop that requests data, the cache line must not be:
 - Returned to Home even when requested.
 - Forwarded directly to the Requester even when instructed by the snoop.

UD Unique Dirty:

- The cache line is present only in this cache.
- The cache line has been modified with respect to memory.
- The cache line must be written back to next level cache or memory on eviction.
- The cache line can be modified without notifying other caches.
- In response to a snoop that requests data, the cache line:
 - Must be returned to Home when requested.
 - Is expected to be forwarded directly to the Requester when instructed by the snoop.

UDP Unique Dirty Partial:

- The cache line is present only in this cache.
- The cache line is unique. The cache line might have some bytes valid, where some includes none or all bytes.
- The cache line has been modified with respect to memory.
- When the cache line is evicted, it must be merged with data from next level cache or memory to form the complete valid cache line.
- The cache line can be modified without notifying other caches.
- In response to a snoop that requests data, the cache line must:
 - Be returned to Home.
 - Not be forwarded directly to the Requester even when instructed by the snoop.

- SC** Shared Clean:
- Other caches might have a shared copy of the cache line.
 - The cache line might have been modified with respect to memory.
 - It is not the responsibility of this cache to write the cache line back to memory on eviction.
 - The cache line cannot be modified without invalidating any shared copies and obtaining unique ownership of the cache line.
 - In response to a snoop that requests data, the cache line:
 - Is required to not return data if RetToSrc bit is not set.
 - Is expected to return data if RetToSrc bit is set.
 - Is expected to be forwarded directly to the Requester when instructed by the snoop.
- SD** Shared Dirty:
- Other caches might have a shared copy of the cache line.
 - The cache line has been modified with respect to memory.
 - The cache line must be written back to next level cache or memory on eviction.
 - The cache line cannot be modified without invalidating any shared copies and obtaining unique ownership of the cache line.
 - In response to a snoop that requests data, the cache line:
 - Must be returned to Home when requested.
 - Is expected to be forwarded directly to the Requester when instructed by the snoop.

A cache is permitted to implement a subset of these states.

4.1.1 Empty cache line ownership

An empty cache line is a cache line that is held in a Unique state to prevent other copies of the cache line existing. None of the data bytes are valid in an empty cache line. This cache line state is UCE or UDP.

The following are examples of when empty cache line ownership can occur:

- A Requester can deliberately obtain an empty cache line before starting a write, to save system bandwidth. A Requester that expects to write to a cache line can obtain an empty cache line with permission to store, instead of obtaining a valid copy of the cache line.
- A Requester can transition into an empty state if the Requester has a copy of the cache line when it requests permission to store. That copy of the cache line is invalidated before the Requester obtains permission to store. At the completion of the request, this results in the Requester having an empty cache line with permission to store.

4.1.2 Ownership of cache line with partial Dirty data

Once ownership of a cache line without data is obtained, the Requester is permitted, but not required, to store to the cache line. If the Requester modifies part of the cache line, the cache line remains partially Unique Dirty. This cache line state is UDP.

4.2 Request types

Protocol requests are categorized as follows:

- For Read request transactions, a data response is provided to the Requester.
- For Dataless request transactions, no data response is provided to the Requester.
- For Write request transactions, data is moved from the Requester.
- For Combined Write request transactions, data is moved from the Requester and a cache maintenance operation is performed.
- For Atomic request transactions, data is moved from the Requester and a data response is provided to the Requester in some request types.
- For Stash request transactions, data can be moved within a system to improve performance.
- Other request transactions:
 - Do not involve any data movement in the system.
 - Can be used to assist with DVM maintenance.
 - Can be used to warm the memory controller for a following read request.

The following subsections enumerate the resulting transactions and their characteristics. See [Chapter 12 Memory Tagging](#) for a description of the Memory Tagging mechanism. See [Table 12-3 on page 12-396](#) for information on the permitted MTE TagOp values for each request. See [Request communicating nodes on page B-500](#) for information on Request communicating nodes.

———— **Note** ————

It is legal for any transaction that is expected to target an HN-F, but not an HN-I, to target an HN-I. This can occur for an incorrect assignment of memory type for a transaction. It is required that the HN-I responds to such a transaction in a protocol-compliant manner.

4.2.1 Read transactions

Read transactions have the following common characteristics:

- Data must be included in the completion response to the Requester, except for MakeReadUnique request. For MakeReadUnique, a data response is optional.
- When Data response is provided, the transferred data can be from the Home Node, another Request Node, or a Subordinate Node.
- In Allocating Read transactions, received data, if cached, must be cached in a system coherent manner.
- In Non-allocating Read transactions, that is, ReadNoSnp and ReadOnce*, received data is not expected to be cached. If cached, data is not cached in a system coherent manner.
- The request can result in a cache state change at the Requester. See [Table 4-4 on page 4-178](#) for expected and permitted initial cache and [Table 4-5 on page 4-178](#) for final cache state at the Requester for each of the Read transactions.
- The request can result in a cache state change at other Request Nodes in the system. See [Table 4-6 on page 4-179](#) for expected and permitted cache states at the peer Request Nodes for each of the Read transactions.

See [Chapter 6 Exclusive accesses](#) for details on Exclusive attribute in read transactions.

ReadNoSnp

Read request by a Request Node to a Non-snoopable address region. Alternatively, from a Home Node to any address region to obtain a copy of the addressed data. See [Table 2-6 on page 2-54](#) for use DMT, Order field, and ExpCompAck values.

ReadNoSnpSep

Read request from a Home Node to Subordinate Node, requesting the Completer to send only a data response. Used when separate completion and data responses are used to complete the read transaction.

ReadOnce

Read request to a Snooppable address region to obtain a snapshot of the coherent data.

ReadOnceCleanInvalid

Read request to a Snooppable address region to obtain a snapshot of the coherent data. It is recommended, but not required, that other cached copies of the cache line are invalidated. If a Dirty copy is invalidated, it must be written back to memory.

————— **Note** —————

ReadOnceCleanInvalid is used instead of ReadOnce or ReadOnceMakeInvalid where the application determines that the data is still Valid, but will not be used in the near future.

Use of ReadOnceCleanInvalid by an application improves cache efficiency by reducing cache pollution.

The following should be considered when using ReadOnceCleanInvalid:

- The invalidation in the ReadOnceCleanInvalid transaction is a hint. Completion of the transaction does not guarantee removal of all cached copies, therefore it cannot be used as a replacement for a CMO.
- Use of the transaction can cause the deallocation of a cache line and therefore caution is needed if the transaction could target the same cache line that other agents in the system are using for Exclusive accesses.

ReadOnceMakeInvalid

Read request to a Snoopable address region to obtain a snapshot of the coherent data. It is recommended, but not required, that other cached copies of the cache line are invalidated. If a Dirty copy is invalidated, it does not need to be written back to memory. All cached copies must be invalidated if the invalidation hint is accepted and a Dirty copy is not written back to memory.

Note

ReadOnceMakeInvalid is used in preference to ReadOnce or ReadOnceCleanInvalid to obtain a snapshot of a data value when the application determines that the cached data is not going to be used again.

The application can free up the caches and also, by discarding Dirty data, avoid an unnecessary WriteBack to memory.

The following should be considered when using ReadOnceMakeInvalid:

- The invalidation in the ReadOnceMakeInvalid transaction is a hint. Completion of the transaction does not guarantee removal of all cached copies, therefore it cannot be used as a replacement for a CMO.
- Use of the transaction can cause the deallocation of a cache line and therefore caution is needed if the transactions could target the same cache line that other agents in the system are using for Exclusive accesses.
- The use of the ReadOnceMakeInvalid transaction can cause the loss of a Dirty cache line. Use of this transaction must be strictly limited to scenarios where it is known that the loss of a Dirty cache line is harmless.
- For a ReadOnceMakeInvalid transaction, it is required that the invalidation of the cache line is committed before the read data response for the transaction. The invalidation of the cache line is not required to have completed at this point, but it must be ensured that any later Write transaction from any agent, which starts after this point, is guaranteed not to be invalidated by this transaction.

ReadClean

Read request to a Snoopable address region to obtain a clean copy of a cache line. This can be used if the Requester is allocating the line to a cache that does not support dirty cache lines, such as an Instruction cache. Data must be provided to the Requester in either UC or SC only.

ReadNotSharedDirty

Read request to a Snoopable address region to carry out a load from the cache line. Data must be provided to the Requester in UC, UD, or SC states only. SD is not permitted.

Note

ReadNotSharedDirty is used instead of ReadShared when the Requester cannot accept data in SD state.

ReadShared

Read request to a Snoopable address region to carry out a load from the cache line. Data must be provided to the Requester in UC, UD, SC, or SD states.

Note

ReadShared is used instead of ReadNotSharedDirty when the Requester is willing to accept data in the SD state.

ReadUnique

Read request to a Snoopable address region to carry out a store to the cache line. Data must be provided to the Requester in UC or UD state only.

ReadPreferUnique Read request to a Snoopable address region requesting a unique copy of a cache line. ReadPreferUnique is used when the Requester prefers, but does not require, the data to be returned in Unique state:

- Data is provided in Unique state unless another Request Node is currently performing an exclusive sequence using the same address. In which case the data is provided in Shared state.
- It is permitted to always provide the data in Shared state to the Requester.

———— **Note** ————

This request is included in this specification to improve the execution efficiency of an exclusive sequence.

MakeReadUnique Read request to a Snoopable address region requesting a unique copy of a cache line. Typical usage is when the Requester has a shared copy of the cache line and wants to obtain permission to store to the cache line.

———— **Note** ————

Because data return is guaranteed if the Requester receives an Invalidating snoop and retention of data is required otherwise, resending a request to obtain a Unique copy of the cache line is never required.

Read request attribute values

This section discusses the attribute values for Read requests across node interfaces.

See [Appendix A Message Field Mappings](#) for complete list.

[Table 4-1](#) lists permitted values for the key attributes in Read requests for Request Node to Home Node.

Table 4-1 RN to HN Read request permitted attribute values

Request	Size (bytes)	Excl	SnpAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
ReadNoSnp	<=64	0,1	0	0010	11	0	0,1
				0011	00,10,11	0	0,1
				0000	00,10	0	0,1
				0001			
				0101			
ReadOnce ReadOnceCleanInvalid	64	0	1	0101	00,10	0	0,1
				1101			
ReadOnceMakeInvalid	64	0	1	0101	00,10	0	0,1

Table 4-1 RN to HN Read request permitted attribute values (continued)

Request	Size (bytes)	Excl	SnpAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
ReadClean	64	0,1	1	0101	00	0,1	1
ReadNotSharedDirty				1101			
ReadShared							
ReadUnique	64	0	1	0101	00	0	1
				1101			
ReadPreferUnique	64	0,1	1	0101	00	0	1
MakeReadUnique				1101			

Table 4-2 lists the permitted values for the key attributes in Read requests for HN-F to SN-F.

Table 4-2 HN-F to SN-F Read request permitted attribute values

Request	Size (bytes)	Excl	SnpAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
ReadNoSnp	<=64	0,1	0	0000 0001 0101 1101	00,01	0	0
ReadNoSnpSep	<=64	0	0	0000 0001 0101 1101	00,01	0	0

Table 4-3 lists the permitted values for the key attributes in Read requests for HN-I to SN-I.

Table 4-3 HN-I to SN-I Read request permitted attribute values

Request	Size (bytes)	Excl	SnpAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
ReadNoSnp	<=64	0,1	0	0010	11	0	0
				0011	00,01,10,11	0	0
				0000	00,01,10	0	0
				0001			
				0101			
ReadNoSnpSep	<=64	0	0	1101			
				0010	11	0	0
				0011	00,01,10,11	0	0
				0000	00,01,10	0	0
				0001			
				0101			
				1101			

Initial cache state at the Requester

Table 4-4 lists the permitted Requester cache states when a Request is sent. The following key is used for Table 4-4 and Table 4-5:

Y	Yes, permitted
-	Not permitted
n/a	Not applicable

Table 4-4 Permitted Requester cache state at the sending of Read request

Request	Initial state						
	UD	UC	SD	SC	I	UDP	UCE
ReadNoSnp	-	-	-	-	Y	-	-
ReadOnce	-	-	-	-	Y	-	Y
ReadOnceCleanInvalid, ReadOnceMakeInvalid	-	-	-	-	Y	-	Y
ReadClean	Y	Y	Y	Y	Y	Y	Y
ReadNotSharedDirty	-	-	-	-	Y	-	Y
ReadShared	-	-	-	-	Y	-	Y
ReadUnique	Y	Y	Y	Y	Y	Y	Y
ReadPreferUnique	-	-	Y	Y	Y	-	Y
MakeReadUnique	-	-	Y	Y	-	-	-

Final cache state at the Requester

Table 4-5 lists the permitted cache state at the Requester at the completion of the transaction.

Table 4-5 Permitted final Requester cache state

Request	Final state						
	UD	UC	SD	SC	I	UDP	UCE
ReadNoSnp	-	-	-	-	Y	-	-
ReadOnce	-	-	-	-	Y	-	-
ReadOnceCleanInvalid, ReadOnceMakeInvalid	-	-	-	-	Y	-	-
ReadClean	-	Y	-	Y	-	-	-
ReadNotSharedDirty	Y	Y	-	Y	-	-	-
ReadShared	Y	Y	Y	Y	-	-	-
ReadUnique	Y	Y	-	-	-	-	-

Table 4-5 Permitted final Requester cache state (continued)

Request	Final state						
	UD	UC	SD	SC	I	UDP	UCE
ReadPreferUnique	Y	Y	Y	Y	-	-	-
MakeReadUnique(non-Excl)	Y	Y	-	-	-	-	-
MakeReadUnique(Excl)	Y	Y	Y	Y	-	-	-

Peer cache state

Table 4-6 lists the permitted cache state at the peer Request Nodes at the completion of the transaction.

In response to a request, the Home must send the appropriate Snoops to ensure cached lines at the peer caches are either an expected or permitted final state.

Table 4-6 Permitted peer cache state at the completion of a request

Request	Peer final state							
	UD	UC	SD	SC	I	UDP	UCE	NoChange
ReadNoSnp	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a
ReadOnce	Y	Y	Y	Y	Y	Y	Y	Y
ReadOnceCleanInvalid, ReadOnceMakeInvalid	Y	Y	Y	Y	Y	Y	Y	Y
ReadClean	-	-	Y	Y	Y	-	-	-
ReadNotSharedDirty	-	-	Y	Y	Y	-	-	-
ReadShared	-	-	Y	Y	Y	-	-	-
ReadUnique	-	-	-	-	Y	-	-	-
ReadPreferUnique	-	-	Y	Y	Y	-	-	-
MakeReadUnique ^a	-	-	-	-	Y	-	-	-

a. For MakeReadUnique(Excl), it is possible that peer caches are not required to change state.

4.2.2 Dataless transactions

Request Nodes use Dataless transactions to perform coherent actions without the transfer of data from or to the Requester. The Dataless transactions, grouped for their common functionality, are:

- CleanUnique, MakeUnique
- Evict
- Independent Stash transactions
 - StashOnceUnique, StashOnceSepUnique, StashOnceShared, StashOnceSepShared
- Cache Maintenance transactions
 - CleanShared, CleanSharedPersist, CleanSharedPersistSep, CleanInvalid, MakeInvalid

Dataless transactions have the following common characteristics:

- Data must not be included in the completion response.
- The Request can result in data movement among other agents in the system.
- The Request can result in a cache state change at the Requester.
See [Table 4-10 on page 4-185](#) for expected and permitted initial cache and [Table 4-11 on page 4-185](#) for final cache state at the Requester for each of the Dataless transactions.
- The Request can result in a cache state change at the other Request Nodes in the system.
See [Table 4-12 on page 4-186](#) for expected and permitted cache states at the peer Request Nodes for each of the Dataless transactions.

See [Chapter 6 Exclusive accesses](#) for details on Exclusive attribute in Dataless transactions.

CleanUnique

Request to a Snooperable address region to change the cache state at the Requester to Unique to carry out a store to the cache line. Typical usage is when the Requester has a shared copy of the cache line and wants to obtain permission to store to the cache line. Any dirty copy of the cache line at a snooper cache must be written back to the memory.

MakeUnique

Request to a Snooperable address region to obtain ownership of the cache line without a data response. This request is used only when the Requester guarantees that it will carry out a store to all bytes of the cache line. Any dirty copy of the cache line at a snooper cache must be invalidated without carrying out a data transfer.

Evict

Used to indicate that a Clean cache line is no longer cached by the Request Node.

StashOnceUnique, StashOnceSepUnique

Request to a Snooperable address region to attempt to move the addressed cache line to a targeted cache to enable the target to store that line. The request includes:

- A valid node ID of another Request Node as the Stash target, along with an optional ID of a Logical Processor within that node. When a valid target is not specified, the addressed cache line can be fetched to be cached at the request Completer.
- It is recommended, but not required, that the other agent is snoopered to indicate that it obtains the addressed cache line and ensures that it is in a cache state suitable for writing to the cache line.
- The DataPull request from the target Request Node is treated as a ReadUnique Request.

See [Chapter 7 Cache Stashing](#).

StashOnceShared, StashOnceSepShared

Request to a Snoopable address region to attempt to move the addressed cache line to a targeted cache. The request includes:

- The node ID of another Request Node. Optionally, the request can include the ID of a Logical Processor within that node. When a valid target is not specified, the addressed cache line can be fetched to be cached at the request Completer.
- It is recommended, but not required, that the other agent is snooped to indicate that it obtains the addressed cache line.
- The DataPull request from the target Request Node is treated as ReadNotSharedDirty.

See [Chapter 7 Cache Stashing](#).

Cache Maintenance transactions

A *Cache Maintenance Operation* (CMO) assists with software cache management. The protocol includes the following five transactions to support a Cache Maintenance Operation:

CleanShared

The completion response to a CleanShared request ensures that all cached copies are changed to a Non-dirty state and any Dirty copy is written back to memory.

CleanSharedPersist

The completion response to a CleanSharedPersist request ensures that all cached copies are changed to a Non-dirty state and any Dirty cached copy is written back to the *Point of Persistence* (PoP).

CleanSharedPersistSep

The Persist or combined CompPersist completion response to a CleanSharedPersistSep request ensures that all cached copies are changed to a Non-dirty state and any Dirty cached copy is written back to the PoP.

Functionality of CleanSharedPersistSep is similar to CleanSharedPersist but allows two separate responses to the Requester.

When sending a persistent CMO, it is expected, but not required, that a Requester uses a CleanSharedPersistSep transaction instead of CleanSharedPersist.

Such a Requester must support receiving both separate Comp and Persist responses and a combined CompPersist response.

CleanInvalid

The completion response to a CleanInvalid request ensures that all cached copies are invalidated. The request requires that any cached Dirty copies must be written to memory.

MakeInvalid

The completion response to a MakeInvalid request ensures that all cached copies are invalidated. The request permits that any cached Dirty copies are discarded.

The following characteristics are common to all five CMO transactions:

- The Resp field value in the Comp, indicating cache state, must be ignored by both the Requester and the Home.
- Sending of a CMO transaction to the interconnect from an RN and from the interconnect to an SN is controlled by the **BROADCASTPERSIST (BP)** and **BROADCASTCACHEMAINTENANCE (BCM)** interface signals. See [Optional interface broadcast signals on page 16-482](#).

Note

Permitting Cache Maintenance Operations to be forwarded downstream of the Home Node incorporates system topologies where some observers might directly access locations downstream of the Home Node and software cache maintenance is required to make cached data visible to such observers.

- Cacheable and SnpAttr bit values must be observed.
- MemAttr values on a request received at Home must be preserved when the request is propagated to the Subordinate, except when it is known that the Subordinate has only Normal memory, in which case the MemAttr bit Device can be set to Normal.
- Order field must not be asserted:
 - A CMO intended for a particular address must not be sent to the interconnect before all previous transactions sent to the same address that can allocate the data in the Requester caches have completed.
 - A transaction intended for a particular address that can allocate data in Requester caches must not be sent to the interconnect before a previous CMO sent to the same address has completed.
 - A Completer is permitted, but not required, to wait for WriteData to send a Persist response. Examples of when a Completer can send an early Persist is when the Completer does not support Persistence on that memory location or the request encounters a Non-data Error.
- A CMO is permitted, but not required, to be combined with a Write transaction to the same address when the write is ahead of the CMO. See [Combined Write requests on page 4-192](#).

Persistent CMO handling at Home

This section discusses the PoP at the Home and downstream of the Home. This section also introduces Deep attribute in Persistent CMO.

Point of Persistence at Home

If the Home is the PoP, then for CleanSharedPersistSep:

- The Home is permitted to not forward the CleanSharedPersistSep request to the Subordinate. When the Home decides not to forward the CleanSharedPersistSep request, it must return a Persist response to the Requester.
- When the Home sends a Persist response, it is permitted, but not required, to combine it with Comp and return a single CompPersist response to the Requester.

Point of Persistence downstream of Home

If the PoP is downstream of the Home, then for CleanSharedPersistSep:

- The Home must send the request downstream.
- The Subordinate Node must return a Comp response only after it guarantees that it has accepted the request and will not return a RetryAck response.
- When a Subordinate Node can guarantee all previous writes to the same address in non-volatile memory are persistent, it must also return Persist response to the Requester or Home. The address location will also contain the updated value even after the removal of power.
- The Home receives a Persist response from downstream, it must forward the Persist response to the Requester:
 - The Subordinate is permitted, but not required, to return a combined CompPersist response to the Home.
 - The Home is permitted, but not required, to wait for the Persist response from the Subordinate. Permitting a Home to wait for a Persist response enables the Home to send a combined CompPersist response to the Requester instead of returning separate Comp and Persist responses.
- If the target is volatile memory, the Persist response can be given immediately. Such a situation must not return an error.

Deep Persistent CMO

For high availability expectations, systems with non-volatile memory require guarantees that operation-critical data is persevered, even when the power and the back up battery fail simultaneously. The guarantee can be provided by a system by adding a mechanism to push previous writes to the Point of Deep Persistence. This specification supports this feature using an attribute, called Deep, on Persistent CMO transactions.

If the Completer of the request with Deep asserted does not support the Deep attribute, the Completer can ignore the attribute value and treat the request as having the Deep attribute deasserted. An error response must not be given to indicate that Deep persistence is not supported. See [Deep persistence](#), [Deep](#) on page 13-434.

Dataless request attribute values

This section discusses the attribute values for Dataless requests across node interfaces.

See [Appendix A Message Field Mappings](#) for complete list.

[Table 4-7](#) lists the values permitted for key attributes in Dataless requests from Request Node to Home Node.

Table 4-7 RN to HN Dataless request permitted attribute values

Request	Size (bytes)	Excl	SnpcAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
CleanUnique	64	0,1	1	0101 1101	00	0	1
MakeUnique	64	0	1	0101 1101	00	0	1
Evict	64	0	1	0101	00	0	0
StashOnceUnique StashOnceSepUnique StashOnceShared StashOnceSepShared	64	0	1	0101 1101	00	0,1	0
CleanShared CleanSharedPersist CleanSharedPersistSep	64	0	1	0101 1101	00 ^a	0	0
CleanInvalid MakeInvalid		0	0	0010 0011 0000 0001 0101 1101	00 ^a	0	0

a. The field is inapplicable and must be set to zero.

Table 4-8 lists the values permitted for key attributes in Dataless requests from HN-F to SN-F.

Table 4-8 HN-F to SN-F Dataless request permitted attribute values

Request	Size (bytes)	Excl	SnpAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
CleanShared	64	0	0	0000	00 ^a	0	0
CleanSharedPersist				0001			
CleanSharedPersistSep				0101			
CleanInvalid				1101			
MakeInvalid							

a. The field is inapplicable and must be set to zero.

Table 4-9 lists the values permitted for key attributes in Dataless requests from HN-I to SN-I.

Table 4-9 HN-I to SN-I Dataless request permitted attribute values

Request	Size (bytes)	Excl	SnpAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
CleanShared	64	0	0	0010	00 ^a	0	0
CleanSharedPersist				0011			
CleanSharedPersistSep				0000			
CleanInvalid				0001			
MakeInvalid				0101			
				1101			

a. The field is inapplicable and must be set to zero.

Initial cache state at the Requester

Table 4-10 lists the permitted Requester cache states when a request is sent. The following key is used for Table 4-10, Table 4-11, and Table 4-12 on page 4-186:

Y Yes, permitted
- Not permitted

Table 4-10 Permitted Requester cache state at the sending of Dataless request

Request	Initial state						
	UD	UC	SD	SC	I	UDP	UCE
CleanUnique	Y	Y	Y	Y	Y	-	Y
MakeUnique	-	Y	Y	Y	Y	-	Y
Evict	-	-	-	-	Y	-	-
StashOnceUnique StashOnceSepUnique	-	-	-	-	Y	-	-
StashOnceShared StashOnceSepShared	-	-	-	-	Y	-	-
CleanShared CleanSharedPersist CleanSharedPersistSep	-	Y	-	Y	Y	-	-
CleanInvalid	-	-	-	-	Y	-	-
MakeInvalid	-	-	-	-	Y	-	-

Cache states for Dataless transactions

This section describes *Final cache state at the Requester* and *Peer cache state on page 4-186* at the completion of a Dataless transaction.

Final cache state at the Requester

Table 4-11 lists the permitted cache state at the Requester at the completion of the transaction.

Table 4-11 Permitted final Requester cache state

Request	Final state						
	UD	UC	SD	SC	I	UDP	UCE
CleanUnique	Y	Y	-	-	-	-	Y
MakeUnique	Y	-	-	-	-	-	-
Evict	-	-	-	-	Y	-	-
StashOnceUnique StashOnceSepUnique	-	-	-	-	Y		-
StashOnceShared StashOnceSepShared	-	-	-	-	Y		-

Table 4-11 Permitted final Requester cache state (continued)

Request	Final state						
	UD	UC	SD	SC	I	UDP	UCE
CleanShared	-	Y	-	Y	Y	-	-
CleanSharedPersist							
CleanSharedPersistSep							
CleanInvalid	-	-	-	-	Y	-	-
MakeInvalid	-	-	-	-	Y	-	-

Peer cache state

Table 4-12 lists the expected and permitted cache state at the peer Request Node at the completion of the Dataless transaction. In response to a request, the Home must send appropriate snoop to transition cached line at the peer caches to either expected or permitted final states.

Table 4-12 Permitted peer cache state at the completion of a request

Request	Peer final state							
	UD	UC	SD	SC	I	UDP	UCE	NoChange
CleanUnique	-	-	-	-	Y	-	-	-
MakeUnique	-	-	-	-	Y	-	-	-
CleanShared	-	Y	-	Y	Y	-	-	-
CleanSharedPersist								
CleanSharedPersistSep								
CleanInvalid	-	-	-	-	Y	-	-	-
MakeInvalid	-	-	-	-	Y	-	-	-

The Peer Request Node cache state at the completion of Evict, StashOnceUnique, StashOnceSepUnique, StashOnceShared, and StashOnceSepShared is not applicable.

4.2.3 Write transactions

Write transactions move data from a Requester to a Completer, this might be the next level cache, memory, or a peripheral. The data being transferred, depending on the transaction type, can be coherent or non-coherent. Each write transaction must assert appropriate byte enables with the data.

Immediate Write transactions

Immediate Write transactions, also known as Non-CopyBack transactions, are a subclass of Write transactions. Immediate Write transactions transfer data from Request Nodes to Home Nodes without initially obtaining coherent ownership of the data. Immediate Write transactions are also used to transfer data from Home Nodes to Subordinate Nodes.

Each Immediate Write transaction must assert the appropriate byte enables with the data. Immediate Write transactions can require snooping of other agents in the system.

In Immediate Write requests, except WriteNoSnpZero and WriteUniqueZero, DWT flow between the Request Node and the Subordinate Node is permitted only when the original request from the Request Node does not use OWO.

DWT flow between a Request Node and a Subordinate Node in WriteNoSnpZero and WriteUniqueZero is never permitted.

WriteNoSnpFull

Write a full cache line of data from a Request Node to a Non-snoopable address region, or write for a full cache line of data to any address region from the Home to Subordinate. All byte enables must be asserted.

WriteNoSnpPtl

Write up to a cache line of data from a Request Node to a Non-snoopable address region, or write up to a cache line of data to any address region from the Home to Subordinate. Byte enables must be asserted for the appropriate byte lanes, including none or all, within the specified data size and deasserted in the rest of the data transfer.

WriteNoSnpZero

Write data value of zero without transferring data bytes from a Request Node to a Non-snoopable address region, or write data value of zero without transferring data bytes to any address region from Home to Subordinate.

WriteUniqueFull

Write to a Snoopable address region. Write a full cache line of data to the next-level cache or memory when the cache line is Invalid at the Requester. All byte enables must be asserted.

WriteUniquePtl

Write to a Snoopable address region. Write up to a cache line of data to the next-level cache or memory when the cache line is Invalid at the Requester. Byte enables must be asserted for the appropriate byte lanes within the specified data size and deasserted in the rest of the data transfer.

WriteUniqueZero

Write to a Snoopable address region. Write without data bytes when the data value is zero.

WriteUniqueFullStash

Write to a Snoopable address region. Write a full cache line of data to the next-level cache or memory when the cache line is Invalid at the Requester. Also includes a request to the Stash target node to obtain the addressed cache line. All byte enables must be asserted.

WriteUniquePtlStash

Write to a Snoopable address region. Write up to a cache line of data to the next-level cache or memory when the cache line is Invalid at the Requester. Also includes a request to the Stash target node to obtain the addressed cache line. Byte enables must be asserted for the appropriate byte lanes within the specified data size and deasserted in the remainder of the data transfer.

CopyBack transactions

CopyBack transactions are a subclass of Write transactions. CopyBack transactions move coherent data from a cache to the next level cache or memory. Each CopyBack transaction must assert the appropriate byte enables with the data. CopyBack transactions do not require the snooping of other agents in the system.

WriteBackFull

WriteBack a full cache line of Dirty data to the next level cache or memory. All byte enables must be asserted except when the write data is CopyBackWrData_I.

WriteBackPtl

WriteBack up to a cache line of Dirty data to the next level cache or memory. All appropriate byte enables, up to all 64, including none or all, must be asserted.

WriteCleanFull

WriteBack a full cache line of Dirty data to the next level cache or memory and retain a Clean copy in the cache. All byte enables must be asserted except when the write data is CopyBackWrData_I.

WriteEvictFull

WriteBack of UniqueClean data to the next-level cache.

- All byte enables must be asserted except when the write data is CopyBackWrData_I.
- The cache line must not propagate beyond its Snoop domain.

WriteEvictOrEvict

WriteBack of Clean data to the next-level cache. This request type is merging of WriteEvictFull and Evict into one request. This allows the Home Node to determine if it is sent data.

- Data might not be sent if the Completer does not accept data.
- If data is sent, then the Data size is a cache line length.
- [Table 4-13](#) indicates the initial state of the cache line when the request is sent:

Table 4-13 LikelyShared value states

LikelyShared	Initial state
0	UC
1	SC

- The cache line must not propagate beyond its Snoop domain.

Write request attribute values

This section discusses the attribute values for Write requests across node interfaces.

Table 4-14 lists the values permitted for key attributes in Write requests from Request Node to Home Node.

Table 4-14 RN to HN Write request attribute values

Request	Size (bytes)	Excl	SnPAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
WriteNoSnPFull	64	0,1	0	0010	11	0	0
				0011	00,11	0	0
					10	0	0,1
				0000	00	0	0
				0001	10	0	0,1
				0101			
				1101			
WriteNoSnPPtl	<=64	0,1	0	0010	11	0	0
				0011	00,11	0	0
					10	0	0,1
				0000	00	0	0
				0001	10	0	0,1
				0101			
				1101			
WriteNoSnPZero	64	0	0	0010	11	0	0
				0011	00,10,11	0	0
				0000	00,10	0	0
				0001	10	0	0,1
				0101			
				1101			
WriteUniqueFull WriteUniqueFullStash	64	0	1	0101	00	0,1	0
				1101	10	0,1	0,1
WriteUniquePtl WriteUniquePtlStash	<=64	0	1	0101	00	0,1	0
				1101	10	0,1	0,1
WriteUniqueZero	64	0	1	0101 1101	00,10	0,1	0
WriteBackFull WriteCleanFull	64	0	1	0101 1101	00	0,1	0
WriteBackPtl	64	0	1	0101 1101	00	0	0
WriteEvictFull	64	0	1	1101	00	0,1	0
WriteEvictOrEvict	64	0	1	1101	00	0,1	1

Table 4-15 lists the values permitted for key attributes in Write requests from HN-F to SN-F.

Table 4-15 HN-F to SN-F Write request attribute values

Request	Size (bytes)	Excl	DoDWT	MemAttr A C D E	Order	LikelyShared	ExpCompAck
WriteNoSnpFull	64	0,1	0,1	0000 0001 0101 1101	00	0 ^a	0 ^a
WriteNoSnpPtl	<=64	0,1	0,1	0000 0001 0101 1101	00	0 ^a	0 ^a
WriteNoSnpZero	64	0	0 ^a	0000 0001 0101 1101	00	0 ^a	0 ^a

a. The field is inapplicable and must be set to zero.

Table 4-16 lists the values permitted for key attributes in Write requests from HN-I to SN-I.

Table 4-16 HN-I to SN-I Write request attribute values

Request	Size (bytes)	Excl	DoDWT	MemAttr A C D E	Order	LikelyShared	ExpCompAck
WriteNoSnpFull	64	0,1	0,1	0010	11	0 ^a	0 ^a
				0011	00,10,11	0 ^a	0 ^a
				0000 0001 0101 1101	00,10	0 ^a	0 ^a
WriteNoSnpPtl	<=64	0,1	0,1	0010	11	0 ^a	0 ^a
				0011	00,10,11	0 ^a	0 ^a
				0000 0001 0101 1101	00,10	0 ^a	0 ^a

Table 4-16 HN-I to SN-I Write request attribute values (continued)

Request	Size (bytes)	Excl	DoDWT	MemAttr A C D E	Order	LikelyShared	ExpCompAck
WriteNoSnzZero	64	0	0 ^a	0010	11	0 ^a	0 ^a
				0011	00,10,11	0 ^a	0 ^a
				0000	00,10	0 ^a	0 ^a
				0001			
				0101			
				1101			

a. The field is inapplicable and must be set to zero.

Initial cache state at the Requester

Table 4-17 lists the permitted Requester cache states when a request is sent. The following key is used:

Y Yes, permitted
- Not permitted

Table 4-17 Permitted Requester cache state at the sending of a Write request

Request	Initial state						
	UD	UC	SD	SC	I	UDP	UCE
WriteNoSnzFull WriteNoSnzPtl	-	-	-	-	Y	-	-
WriteNoSnzZero	-	-	-	-	Y	-	-
WriteUniqueFull WriteUniquePtl WriteUniqueZero	-	-	-	-	Y	-	-
WriteUniqueFullStash WriteUniquePtlStash	-	-	-	-	Y	-	-
WriteBackFull	Y	-	Y	-	-	-	-
WriteBackPtl	-	-	-	-	-	Y	-
WriteCleanFull	Y	-	Y	-	-	-	-
WriteEvictFull	-	Y	-	-	-	-	-
WriteEvictOrEvict	-	Y	-	Y	-	-	-

Final cache state at the Requester

The permitted Requester cache state at the completion of a Write transaction, except for WriteCleanFull, is Invalid.

The permitted Requester cache state at the completion of a WriteCleanFull transaction is UC or SC.

Peer cache state

The Peer Request Node cache state at the completion of WriteNoSnPtl, WriteNoSnPFull, and WriteNoSnPZero is not applicable.

The Peer Request Node cache state at the completion of WriteUniquePtl, WriteUniqueFull, WriteUniqueZero, WriteUniquePtlStash, and WriteUniqueFullStash must be Invalid.

The Peer Request Node cache state at the completion of CopyBack requests is not changed. The Home Node is not required to snoop the Peer Request Nodes to change their cache state.

4.2.4 Combined Write requests

This specification supports the combining of Write transactions with Cache Maintenance transactions when both are to the same address. The ability to combine the two requests to the same address is useful when a CMO or PCMO transaction reaches a point in the system where a Write operation must be completed before the CMO or PCMO transaction can be initiated. The use of a single Combined Write transaction avoids the need to serialize the Write and CMO or PCMO transactions. The point where the two requests are combined can be a Request Node or a Home Node.

Table 4-18 and Table 4-19 on page 4-193 show the Write, CMO, and PCMO combinations for which combining is permitted. Empty table cells indicate a combination that is not permitted or not applicable.

———— Note ————

Deep is an attribute on persistent CMO requests. Deep has not been listed explicitly as a CMO type in Table 4-18 and Table 4-19 on page 4-193.

When a Persistent CMO is combined with a write, the Persistent CMO is treated as a CleanSharedPersistSep, that is, in addition to a completion response, a separate Persist response is required for the CMO part of the request.

Table 4-18 and Table 4-19 on page 4-193 show the permitted combinations of Write and CMO requests. Table 4-18 and Table 4-19 on page 4-193 use the following key:

Y Yes, permitted
- Not permitted

Table 4-18 Permitted combinations of Write and CMO for RN to HN requests

Write type	Persistent CMO	Non-persistent CMO		
	(With separate Persist response)	CleanShared	CleanInvalid	MakeInvalid
WriteNoSnPFull WriteNoSnPtl	Y	Y	Y	-
WriteUniqueFull WriteUniquePtl	Y	Y	-	-
WriteUniqueStashFull WriteUniqueStashPtl	-	-	-	-
WriteBackFull	Y	Y	Y	-
WriteBackPtl	-	-	-	-
WriteCleanFull	Y	Y	-	-
WriteEvictFull	-	-	-	-

Table 4-19 Permitted combinations of Write and CMO for HN to SN requests

Write type	Persistent CMO	Non-persistent CMO		
	(With separate Persist response)	CleanShared	CleanInvalid	MakeInvalid
WriteNoSnpFull	Y	Y	Y	-
WriteNoSnpPtl				

Examples of how combining of a Write request with Cache Maintenance is useful are:

- Combining WriteBack with CleanShared and CleanSharedPersist, supports Request Nodes that transition the cache line to Invalid when cleaned by a CMO irrespective of the type of CMO.
- Combining WriteUnique with CleanShared supports the case when the CleanSharedPersist target is known to not support Persistent transactions. Therefore, the CleanSharedPersist request needs to be converted to CleanShared by the Requester.

For each Write request the Combined Write requests are:

- WriteNoSnpFull:
 - WriteNoSnpFullCleanInv
 - WriteNoSnpFullCleanSh
 - WriteNoSnpFullCleanShPerSep
- WriteNoSnpPtl:
 - WriteNoSnpPtlCleanInv
 - WriteNoSnpPtlCleanSh
 - WriteNoSnpPtlCleanShPerSep
- WriteUniqueFull:
 - WriteUniqueFullCleanSh
 - WriteUniqueFullCleanShPerSep
- WriteUniquePtl:
 - WriteUniquePtlCleanSh
 - WriteUniquePtlCleanShPerSep
- WriteBackFull:
 - WriteBackFullCleanInv
 - WriteBackFullCleanSh
 - WriteBackFullCleanShPerSep
- WriteCleanFull:
 - WriteCleanFullCleanSh
 - WriteCleanFullCleanShPerSep

Characteristics

A Combined Write request is permitted for both CopyBack and Immediate writes.

All permitted behaviors of the Combined Write request are the same as if the write and CMO are sent separately, except that:

- WriteNoSnp(Excl) is not permitted to be combined with a CMO.
- TagOp setting of *Match* is not permitted in Write*CMO.

A Home receiving a Combined Write request from a Request Node is permitted to forward the Combined Write to the Subordinate Node if both the write and the CMO or PCMO in the request need to be sent downstream. The Home is also permitted to use DWT for such a Write request if the write from the Request Node is an Immediate write and ExpCompAck is set to zero.

Where an uncombined CMO from a Request Node results in the cache line being evicted from a cache at the Home or a Dirty copy is passed in a Snoop response, the CMO propagated to the Subordinate can be combined with the write back to the Subordinate.

The receiver of a Combined Write request is permitted, but not required, to separate the write and the CMO request and process them separately. In such a case, the CMO request must be ordered behind the write. Once the requests are separated, the Completer is permitted to interleave requests to the same address between the write and the CMO transaction.

The Size field value in a combined request corresponds to the size of Data in the Write request. The CMO is always on a 64-byte granularity.

The MemAttr and SnpAttr field values in a Combined Write request correspond to the memory attributes of the Write request. When the write and the CMO transactions are separated, the Write transaction inherits the MemAttr and SnpAttr values of the original combined request. The SnpAttr and Cacheable bit values of the separated CMO transaction must be set to the most pervasive.

4.2.5 Atomic transactions

An Atomic transaction permits a Requester to issue a transaction with a memory address and an operation to be performed on the memory address to the interconnect. This transaction type moves the operation closer to where the data resides and is useful for atomically executing an operation and updating the memory location in a performance efficient manner.

Without an Atomic transaction, an atomic operation has to be executed using a sequence of memory accesses. These accesses might rely on Exclusive reads and writes.

By using an Atomic transaction:

- A more deterministic latency can be estimated for atomic operations.
- The blocking period of access to the memory location being modified is reduced, which then reduces the impact on the forward progress of memory accesses by other agents.
- Providing fairness among different Requesters accessing a memory location becomes simpler, because accessing of that memory location by an atomic operation is arbitrated at the *Point of Serialization* (PoS) or *Point of Coherence* (PoC).

This specification defines the following terms relating to atomic operations and Atomic transactions:

Atomic operation	The execution of a function involving multiple data values such that, the loading of the original value, the execution of the function, and the storing of the updated value, occurs in an atomic manner. This means that no other agent has access to the location during the entire operation.
Atomic transaction	A transaction that is used to pass an atomic operation, along with the data values required for the execution of the atomic operation, from one agent in a system to another, so that the atomic operation can be carried out by a different component in the system than the component that requires the operation to be performed.

Atomic transaction types

This specification defines four Atomic transaction types:

- AtomicStore
- AtomicLoad
- AtomicSwap
- AtomicCompare

See [Chapter 12 Memory Tagging](#) for a description of the Memory Tagging mechanism.

For information on the permitted MTE TagOp values for each Atomic request see [Table 12-3 on page 12-396](#).

The following terminology is used to refer to the different data elements in the execution of an atomic operation:

TxnData	The write data in the AtomicLoad, and AtomicStore transactions.
CompareData	The compare value in the AtomicCompare transaction.
SwapData	The swap value in the AtomicCompare, and AtomicSwap transactions.
InitialData	The content of the addressed location before the atomic operation.

Enumeration of the four Atomic transaction types is as follows:

AtomicStore	<ul style="list-style-type: none"> • Sends a single data value with an address and the atomic operation to be performed. • The target, a Home Node or a Subordinate Node, performs the required operation on the address location specified with the data supplied in the Atomic transaction. • The target returns a completion response without data. • Unlike in AtomicLoad transactions, the original value of AtomicStore transactions at the addressed location is not returned to the Requester. • Number of operations supported is 8.
--------------------	--

[Table 4-20](#) shows the eight operations supported by the AtomicStore transaction.

Each of the AtomicStore operations apply to 1 byte, 2 byte, 4 byte, or 8 byte data sizes.

Table 4-20 AtomicStore operations

Operation	Action
STADD	Update location with: (TxnData + InitialData)
STCLR	Update location with bitwise: (InitialData AND (NOT TxnData))
STEOR	Update location with bitwise: (InitialData XOR TxnData)
STSET	Update location with bitwise: (InitialData OR TxnData)
STSMAX	Update location with TxnData if: (((Signed INT) TxnData - (Signed INT) InitialData) > 0)
STSMIN	Update location with TxnData if: (((Signed INT) TxnData - (Signed INT) InitialData) < 0)
STUMAX	Update location with TxnData if: (((Unsigned INT) TxnData - (Unsigned INT) InitialData) > 0)
STUMIN	Update location with TxnData if: (((Unsigned INT) TxnData - (Unsigned INT) InitialData) < 0)

AtomicLoad

- Sends a single data value with an address and the atomic operation to be performed.
- The target, a Home Node or a Subordinate Node, performs the required operation on the address location specified with the data value supplied in the Atomic transaction.
- The target returns the completion response with data. The data value is the original value at the addressed location.
- Number of operations supported is 8.

Table 4-21 shows the eight operations supported by the AtomicLoad transaction.

Each of the AtomicLoad operations applies to 1 byte, 2 byte, 4 byte, or 8 byte data sizes.

Table 4-21 AtomicLoad operations

Operation	Action
LDADD	Update location with: (TxnData + InitialData)
LDCLR	Update location with bitwise: (InitialData AND (NOT TxnData))
LDEOR	Update location with bitwise: (InitialData XOR TxnData)
LDSET	Update location with bitwise: (InitialData OR TxnData)
LDSMAX	Update location with TxnData if: (((Signed INT) TxnData - (Signed INT) InitialData) > 0)
LDSMIN	Update location with TxnData if: (((Signed INT) TxnData - (Signed INT) InitialData) < 0)
LDUMAX	Update location with TxnData if: (((Unsigned INT) TxnData - (Unsigned INT) InitialData) > 0)
LDUMIN	Update location with TxnData if: (((Unsigned INT) TxnData - (Unsigned INT) InitialData) < 0)

AtomicSwap

- Sends a single data value, the swap value, together with the address of the location to be operated on.
- The target, a Home Node or a Subordinate Node, swaps the value at the address location with the data value supplied in the transaction.
- The target returns the completion response with data. The data value is the original value at the addressed location.
- Number of operations supported is 1.

AtomicCompare

- Sends two data values, the compare value and the swap value, with the address of the location to be operated on.
- The target, a Home Node or a Subordinate Node, compares the value at the addressed location with the compare value:
 - If the values match, the target writes the swap value to the addressed location.
 - If the values do not match, the target does not write the swap value to the addressed location.

- The target returns the completion response with data. The data value is the original value at the addressed location.
- Number of operations supported is 1.

Other common characteristics of Atomic transactions are:

- Data must be included in the completion response to the Requester, except for AtomicStore transaction. For AtomicStore, the completion response does not include the data response.
 - When data is returned, inbound data size must be the same as the outbound data size, except for an AtomicCompare transaction. In AtomicCompare, inbound data size must be half of the outbound data size.
 - The data value in the response data must be the original value at the addressed location.
 - The received data must not be cached at the Requester.
- Byte enables must be asserted for all valid data in the inbound and outbound data messages.
- The request can result in a cache state change at other Request Nodes in the system. The peer Request Node cache state must be Invalid at the completion of the request.
- Atomic transactions cannot use DMT nor DWT flows.

A Requester that has a cached copy of the line on which it must perform an atomic operation can do the following:

- If the cache line is Unique, it can perform the atomic operation locally without generating an Atomic transaction.
- If the cache line is Shared but not Dirty, it can either:
 - Generate a ReadUnique, CleanUnique, or MakeReadUnique to gain ownership of the cache line and perform the atomic operation locally.
 - Invalidate the local copy and send the Atomic transaction to the interconnect.
- If the cache line is Shared Dirty, it can either:
 - Generate a ReadUnique, CleanUnique, or MakeReadUnique, gain ownership of the cache line, and perform the operation locally.
 - WriteBack and Invalidate the local copy and then send the Atomic transaction to the interconnect.
- Optionally, in all the above cases, the Requester is permitted, but not required, to send the Atomic transaction with the SnoopMe bit set to direct the interconnect to send a Snoop request to the Requester to invalidate, and if necessary, extract the cached copy. See [SnoopMe on page 13-441](#).

Atomic request attribute values

This section discusses the attribute values for Atomic requests across node interfaces.

Table 4-22 lists the permitted values for attributes for Atomic requests from Request Node to Home Node.

Table 4-22 RN to HN Atomic request attribute values

Request	Size (bytes)	SnoopMe	SnpAttr	MemAttr A C D E	Order	LikelyShared	ExpCompAck
AtomicStore	1, 2, 4, 8	0	0	0010	11	0	0
AtomicLoad				0011	00,10,11	0	0
AtomicSwap				0000	00,10	0	0
				0001			
				0101			
				1101			
	0,1	1	0101	00,10	0	0	
			1101				
AtomicCompare	2, 4, 8, 16, 32	0	0	0010	11	0	0
				0011	00,10,11	0	0
				0000	00,10	0	0
				0001			
				0101			
				1101			
	0,1	1	0101	00,10	0	0	
			1101				

Table 4-23 lists the permitted values for attributes for Atomic requests from HN-F to SN-F.

Table 4-23 HN-F to SN-F Atomic request attribute values

Request	Size (bytes)	SnoopMe	DoDWT	MemAttr A C D E	Order	LikelyShared	ExpCompAck	
AtomicStore	1, 2, 4, 8	0 ^a	0	0000	00	0 ^a	0 ^a	
AtomicLoad				0001				
AtomicSwap				0101				
				1101				
AtomicCompare	2, 4, 8, 16, 32	0 ^a	0	0000	00	0 ^a	0 ^a	
				0001				
				0101				
				1101				

a. The field is inapplicable and must be set to zero.

Table 4-24 lists the permitted values for attributes for Atomic requests from HN-I to SN-I.

Table 4-24 HN-I to SN-I Atomic request attribute values

Request	Size (bytes)	SnoopMe	DoDWT	MemAttr A C D E	Order	LikelyShared	ExpCompAck
AtomicStore	1, 2, 4, 8	0 ^a	0	0010	11	0 ^a	0 ^a
AtomicLoad				0011	00, 10, 11	0 ^a	0 ^a
AtomicSwap				0000	00, 10	0 ^a	0 ^a
				0001			
				0101			
				1101			
AtomicCompare	2, 4, 8, 16, 32	0 ^a	0	0010	11	0 ^a	0 ^a
				0011	00, 10, 11	0 ^a	0 ^a
				0000	00, 10	0 ^a	0 ^a
				0001			
				0101			
				1101			

a. The field is inapplicable and must be set to zero.

Communicating node pair

See [Table B-1 on page B-500](#) for expected and permitted node pairs for each Atomic transaction.

Initial cache state at the Requester

The Requester cache state permitted at the issue of the Atomic transaction is any state.

If the Requester at the time of issuing an Atomic transaction determines the cache state to not be Invalid, or cannot determine that the cache state is Invalid, then it must set the value of SnoopMe in the Atomic request to 1.

Final cache state at the Requester

The Requester cache state permitted at the completion of an Atomic transaction is Invalid.

Peer cache state

The peer Request Node cache state at the completion of Atomic transactions is Invalid.

4.2.6 Other transactions

This section describes the protocol transactions that carry out miscellaneous actions.

See [Chapter 12 Memory Tagging](#) for a description of the Memory Tagging mechanism.

For information on the permitted MTE TagOp values for each miscellaneous request see [Table 12-3 on page 12-396](#).

See [Table B-1 on page B-500](#) for expected and permitted node pairs for other transactions.

DVM transactions

DVM transactions are used for virtual memory system maintenance.

DVMOp DVM Operation. Actions include the passing of messages between components within a distributed virtual memory system. See [Chapter 8 DVM Operations](#) for details.

Prefetch transaction

The Prefetch target transaction is used to speculatively fetch data from main memory.

PrefetchTgt Prefetch Target. A Request to a Snooperable memory address, sent from a Request Node directly to a Subordinate Node:

- The PrefetchTgt transaction does not include a response.
- The request can be used by the Subordinate Node to fetch the data from off-chip memory and buffer it in anticipation of a subsequent Read request to the same location.
- The request does not include a response nor RetryAck. The Requester can deallocate the request as soon as the request is sent.
- The Receiver must accept the request without dependency on receiving of a subsequent Read request to the same address.
- The Receiver is permitted to initiate an internal action or discard the request without any further action.
- Data read from off-chip memory using PrefetchTgt must not hold Subordinate Node resources waiting indefinitely for a future Read request to the same address.
- The following fields are inapplicable and can take any value:
 - TxnID
 - Order
 - Endian
 - Size
 - MemAttr
 - SnpAttr
 - Excl
 - LikelyShared

4.3 Snoop request types

The interconnect generates a Snoop request either in response to a request from a Request Node or due to an internal trigger such as a cache or snoop filter maintenance operation. A Snoop transaction, except for SnpDVMOp, operates on the cached data at the RN-F. A SnpDVMOp transaction carries out a DVM maintenance operation at the target node.

The Home selection of a Snoop to send is based on several criteria:

- Expected or permitted final cache states, required by the request causing the snoop, at the Requester and the snooped nodes.
- Avoid losing any Dirty tags present in the caches being snooped.
- Replacing a Non-forwarding with an equivalent Forwarding snoop, if one exists.
- A Forwarding snoop is permitted to be sent to one RN-F only.
- A stash snoop is permitted to be sent to one RN-F only.
- Snoops are permitted, but not required, to Non-snoopable address locations.

See [Request transactions and corresponding Snoop requests on page 4-204](#).

See [Cache state transitions at a Snoopee on page 4-232](#) for the permitted responses for specific snoop types.

For details of Snoop transaction interaction with the *Memory Tagging Extension* (MTE) see [Chapter 12 Memory Tagging](#).

SnpOnceFwd, SnpOnce

Snoop request to obtain the latest copy of the cache line, preferably without changing the cache line state at the Snoopee:

SnpStashUnique

Snoop request recommending that the Snoopee obtains a copy of the cache line in a Unique state:

- It is expected that the snoop for a StashOnceUnique request is not sent if the cache line is cached in Unique state at the Stash target.
- Permitted, but not required, to send the snoop to the Stash target for WriteUniqueFullStash and WriteUniquePtlStash only if the Snoopee does not have a cached copy of the cache line.
- The Snoopee must not return data with the Snoop response.
- Permits the Snoop response to include a Data Pull.
- Data Pull request in the Snoop response is treated as a ReadUnique.
- Must not change the cache line state at the Snoopee.

SnpStashShared

Snoop request recommending that the Snoopee obtains a copy of the cache line in a Shared state:

- It is expected to not send the snoop if the cache line is cached at the target.
- The Snoopee must not return data with the Snoop response.
- Permits the Snoop response to include a Data Pull.
- Data Pull request in the Snoop response is treated as a ReadNotSharedDirty.
- Must not change the cache line state at the Snoopee.

SnpCleanFwd, SnpClean

Snoop request to obtain a copy of the cache line in Clean state while leaving any cached copy in Shared state. Must not leave the cache line in Unique state.

SnpNotSharedDirtyFwd, SnpNotSharedDirty

Snoop request to obtain a copy of the cache line in SharedClean state while leaving any cached copy in a Shared state. Must not leave the cache line in Unique state.

SnpSharedFwd, SnpShared

Snoop request to obtain a copy of the cache line in Shared state while leaving any cached copy in Shared state. Must not leave the cache line in Unique state.

SnpUniqueFwd, SnpUnique

Snoop request to obtain a copy of the cache line in Unique state while invalidating any cached copies. Must change the cache line to Invalid state.

SnpPreferUniqueFwd, SnpPreferUnique

Snoop request to obtain a copy of the cache line in Unique state while invalidating any cached copies:

- Home is expected to use SnpPreferUniqueFwd or SnpPreferUnique in response to ReadPreferUnique.
- The behavior of the Snoopee is dependent on whether it is executing an exclusive sequence.

SnpUniqueStash

Snoop request to invalidate the cached copy at the Snoopee and recommends that the Snoopee obtains a copy of the cache line in Unique state:

- Permits the Snoop response to include a DataPull.
- Data Pull request in the Snoop response is treated as a ReadUnique.

SnpCleanShared

Snoop request to remove any Dirty copy of the cache line at the Snoopee. Must not leave the cache line in a Dirty state.

SnpCleanInvalid

Snoop request to Invalidate the cache line at the Snoopee and obtain any Dirty copy. Might also be generated by the interconnect without a corresponding request. Must change the cache line to Invalid state.

SnpMakeInvalid

Snoop request to Invalidate the cache line at the Snoopee and discard any Dirty copy:

- Does not return data with the Snoop response, Dirty data is discarded.
- Must change the cache line to Invalid state.

SnpMakeInvalidStash

Snoop request to invalidate the copy of the cache line and recommends that the Snoopee obtains a copy of the cache line in Unique state:

- Snoopee must not return data with the Snoop response, Dirty data must be discarded.
- Permits the Snoop response to include a DataPull.
- Data Pull request in the Snoop response is treated as a ReadUnique.

SnpQuery

SnpQuery probes the state of a cache line at a Request Node:

- Home can send a SnpQuery snoop without any corresponding request from a Requester.
- The Snoop response must include the precise state of the cache line at the targeted Snoopee.

- Snoopee must not return data with the Snoop response.
- The SnpQuery snoop must not change the state of the cache line at the Snoopee.

See [MakeReadUnique transaction on page 4-224](#) and [MakeReadUnique\(Excl\) on page 6-298](#) to see how SnpQuery can be used in the efficient handling of exclusive request flows.

SnpDVMOp

Generated at the interconnect, initiated by the DVMOp request:

- A single DVMOp request generates two snoop requests.
- Returns a single Snoop response for the two Snoop requests.

See [Non-sync type DVM transaction flow on page 8-314](#).

4.4 Request transactions and corresponding Snoop requests

For a required coherency action, a Home has a choice of multiple snoop types that it is permitted to select from. This section describes examples of how a Home selects the snoop to send and the number of snoops it sends.

While responding to a Request, the selection of which snoop to use is determined from the intended outcome, that is the desired final state of the cache line at the Requester and the required or desired cache state at the Snoopee.

See [Request types on page 4-172](#) for required cache state at peer Request Nodes. See [Cache state transitions at a Snoopee on page 4-232](#) for details of Snoopee cache state transitions.

4.4.1 Number of snoops to send

The Home Node can send snoops to more than one Request Node, including to all. In the case of an invalidation, the invalidating snoop must be sent at least to all the cached copies. Whereas for a Non-invalidating snoop, the Home Node is:

- Permitted, but not required, to send the snoop to all Request Nodes with the cached copies.
- Must be able to obtain a copy of the Dirty line. In the case of a cache line in Unique Dirty state, it must send a snoop to the Request Node with the Unique Dirty cached copy.

For Write transactions with stash hint, the Home Node must also send invalidating snoops to all Non-stash target Request Nodes that have a copy of the cache line:

- For WriteUniqueFullStash, the expected snoop to Non-stash target nodes is SnpMakeInvalid.
- For WriteUniquePtlStash, the expected snoop to Non-stash target nodes is SnpCleanInvalid.

A snoop filter or directory can be included within the interconnect to support filtering of snoops.

4.4.2 Selection of snoop to send

A Home Node, based on internal preferences and implementation constraints, might prefer one of the expected snoops or substitute an expected snoop with others. See [Table 4-25 on page 4-205](#) for the expected snoop per Request type.

Table 4-25 shows the snoops expected to be used by the Home Node for a given Request. A Home is permitted to substitute the expected snoop with another snoop that accomplishes the required Snoopee state transition.

Table 4-25 Expected snoop requests per Request from an RN

Request Category	Request	Expected Snoop
Read	ReadNoSnp	None or SnpOnceFwd ^a
	ReadNoSnpSep	n/a
	ReadOnce	SnpOnceFwd ^a
	ReadOnceCleanInvalid	SnpUnique or SnpOnceFwd ^a
	ReadOnceMakeInvalid	SnpUnique or SnpOnceFwd ^a
	ReadClean	SnpCleanFwd
	ReadNotSharedDirty	SnpNotSharedDirtyFwd
	ReadShared	SnpSharedFwd
	ReadUnique	SnpUniqueFwd
	ReadPreferUnique	SnpPreferUniqueFwd
	MakeReadUnique	SnpCleanInvalid or SnpUniqueFwd ^b
Dataless	CleanUnique	SnpCleanInvalid
	MakeUnique	SnpMakeInvalid
	Evict	None
	CleanShared	SnpCleanShared
	CleanSharedPersist CleanSharedPersistSep	SnpCleanShared
	CleanInvalid	SnpCleanInvalid
	MakeInvalid	SnpMakeInvalid
Dataless-stash	StashOnceUnique StashOnceSepUnique	SnpStashUnique
	StashOnceShared StashOnceSepShared	SnpStashShared
Write	WriteNoSnp	None
	WriteNoSnpSep	n/a
	WriteUniqueFull	SnpMakeInvalid
	WriteUniquePtl	SnpCleanInvalid or SnpUnique
	WriteUniqueZero	SnpMakeInvalid
Write-stash	WriteUniqueFullStash	SnpMakeInvalidStash
	WriteUniquePtlStash	SnpUniqueStash

Table 4-25 Expected snoop requests per Request from an RN (continued)

Request Category	Request	Expected Snoop
Write-CopyBack	WriteBack	None
	WriteClean	
	WriteEvictFull	
	WriteEvictOrEvict	
Atomic	AtomicStore	SnpuUnique
	AtomicLoad	SnpuUnique
	AtomicSwap	SnpuUnique
	AtomicCompare	SnpuUnique
Others	DVMOp	SnpuDVMOp
	PCrdReturn	n/a
	PrefetchTgt	

a. Forwarding snoops cannot be used for requests of less than 64B.

b. Home is expected to use SnpuUniqueFwd if it determines that the Requester has lost its copy of the cache line.

The interconnect has the following behavior when generating a snoop request on receipt of a request from a Request Node:

- This specification supports a snoop filter or directory within the interconnect to track the state of cache lines present in RN-F caches. The tracking can be as detailed as knowing each RN-F that has a copy of the cache line, or as nonspecific as knowing that a cache line is present in one of the RN-F caches. Such tracking permits the interconnect to filter unnecessary snooping of an RN-F, for example:
 - If the snoop filter indicates that the cache line is not present in any of the RN-F caches, the interconnect does not send a snoop request.
 - If the cache line in the RN-F caches is already in the required state, for example the received request is ReadShared and all cached copies of the cache line are in SC state, the interconnect does not send a snoop request.
- The interconnect in response to a WriteUniqueFull, WriteUniqueFullStash, MakeUnique, and MakeInvalid must not use the SnpuMakeInvalid snoop request unless either:
 - The transaction TagOp value is *Update*.
 - The interconnect can determine that the Snoopee does not hold Dirty tags.
- The interconnect in response to a MakeReadUnique must not use the SnpuMakeInvalid Snoop request unless the interconnect can determine either that:
 - The Requester still has a cached copy of the cache line and the Snoopee does not have Dirty tags.
 - The Requester has lost its cached copy and the Snoopee does not have a Dirty copy of the cache line.
- It is permitted for the interconnect to generate a snoop request spontaneously without a corresponding request from a Request Node. For example, the interconnect can send a SnpuUnique or SnpuCleanInvalid request as a result of a backward invalidation from a snoop filter or interconnect cache.

- It is permitted for the interconnect to select which snoop request to send. For example:
 - For a WriteUniquePtl request, either a SnpCleanInvalid or SnpUnique snoop request can be sent. Both of these snoop transactions invalidate the cache line and if the cache line is dirty then data is returned with the response. The write data is written to memory once all Snoop responses are received and the partial data has been merged with any dirty data received with the Snoop response.
The only difference in the behavior between the SnpCleanInvalid and SnpUnique snoop requests is that SnpUnique can return data from the UC state but SnpCleanInvalid does not. Using SnpUnique therefore might result in an unnecessary data transfer. This example shows the disadvantage of using SnpUnique instead of SnpCleanInvalid in certain circumstances.
- The interconnect is permitted to:
 - For ReadNotSharedDirty, ReadShared, and ReadClean transactions, use SnpNotSharedDirty or SnpShared or SnpClean.
 - For ReadShared transactions, use SnpNotSharedDirtyFwd or SnpSharedFwd or SnpCleanFwd.
 - For ReadNotSharedDirty and ReadClean transactions, use SnpNotSharedDirtyFwd or SnpCleanFwd.
 - For the ReadOnce transactions, use any Non-forwarding, Non-invalidating snoop types.
 - For the ReadOnceCleanInvalid and ReadOnceMakeInvalid transactions, use any Non-forwarding snoop types except SnpMakeInvalid.
 - For the ReadOnce, ReadOnceCleanInvalid, and ReadOnceMakeInvalid transactions, use Forwarding snoop type SnpOnceFwd.
 - For WriteUniqueFullStash and WriteUniquePtlStash transactions, send SnpStashUnique or SnpMakeInvalidStash to the target Request Node if the target Request Node does not have the cache line.
 - Replace any Invalidating snoop request by the SnpUnique or SnpCleanInvalid request.
 - Replace any Forwarding snoop with a corresponding non-Forwarding type. The receiver is permitted to treat the forward indication as a hint and respond to the snoop with a corresponding non-Forwarding version in a protocol-compliant manner. This is permitted irrespective of the use of MTE.
 - Use of SnpMakeInvalid for MakeInvalid and WriteUniqueZero is permitted only when the Home knows that the Snoopee does not have Dirty tags.

4.5 Response types

Each request can generate one or more responses. Some responses can also include data. A Response is classified as follows:

- [Completion response](#)
- [WriteData response on page 4-210](#)
- [Snoop response on page 4-212](#)
- [Miscellaneous response on page 4-218](#)

4.5.1 Completion response

A completion response is required for all transactions except PCrdReturn and PrefetchTgt. It is typically the last message sent from the Completer to conclude a request transaction. However, the Requester might still send a CompAck response to conclude the transaction. A completion guarantees that the request has reached a PoS or a PoC, where it will be ordered with respect to requests to the same address from any Requester in the system. See [Ordering on page 2-121](#) for details on the Ordering guarantees.

Read and Atomic transaction completion

A Read completion is either in the form of a single response on the RDAT channel using the CompData opcode, or two separate responses, one on the RSP channel using the RespSepData opcode and a second one on the RDAT channel using the DataSepResp opcode. See [Dataless transaction completion on page 4-209](#) for completion without data for the MakeReadUnique transaction.

AtomicLoad, AtomicSwap, and AtomicCompare completion is sent on the RDAT channel and uses the CompData opcode.

The CompData and DataSepResp completion responses include the Resp field that indicates the following:

- Cache state** The final permitted state of the cache line at the Requester for all reads except ReadNoSnp and ReadOnce*.
- Pass Dirty** Indicates if the responsibility for updating memory is passed to the Requester. The assertion of the Pass Dirty bit is shown by _PD in the response name.

When using separate Comp and Data responses, RespSepData also includes the Resp field with Cache state and Pass Dirty indications. The Resp field value in RespSepData must be either inapplicable and set to zero or the same as in the corresponding DataSepResp.

[Table 4-26](#) shows the permitted Read transaction completion, the encoding of the Resp field, and the meaning of the response. A Subordinate Node can send DataSepResp only in response to ReadNoSnpSep, and only CompData in response to ReadNoSnp.

Table 4-26 Permitted Read transaction completion and Resp field encodings

Response	Resp[2:0]	Description
CompData_I DataSepResp_I	0b000	Indicates that a coherent copy of the cache line cannot be kept.
RespSepData_I	0b000	Cache state in this response is not applicable. Cache state must be determined from DataSepResp response.
CompData_UC DataSepResp_UC RespSepData_UC	0b010	The final state of the cache line can be UC, UCE, SC or I, when the cache state in the response is applicable. This response is also permitted for ReadNoSnp and ReadOnce* transactions but the cache line will not be coherent. Responsibility for a Dirty cache line is not being passed.

Table 4-26 Permitted Read transaction completion and Resp field encodings (continued)

Response	Resp[2:0]	Description
CompData_SC DataSepResp_SC RespSepData_SC	0b001	The final state of the cache line can be SC or I. Responsibility for a Dirty cache line is not being passed.
CompData_UD_PD DataSepResp_UD_PD RespSepData_UD_PD	0b110	The final state of the cache line can be UD or SD. Responsibility for a Dirty cache line is being passed.
CompData_SD_PD	0b111	The final state of the cache line must be SD. Responsibility for a Dirty cache line is being passed.

In a response with an error indication, the cache state is permitted to be any value, including reserved values. See [Errors and transaction structure on page 9-344](#).

Dataless transaction completion

A completion for Dataless transactions and the MakeReadUnique transaction without data is sent on the CRSP channel and uses the Comp, CompPersist, CompCMO, or CompStashDone opcode.

CompCMO is the completion message for the CMO and PCMO in a Combined Write transaction. It must be used only in Combined Write transactions. CompCMO can be combined with Persist response as CompPersist opcode.

The Comp response includes the Resp field that indicates the following:

Cache state The final state the cache line is permitted to be in at the Requester, except for CMO transactions. For CMO transactions, the cache state field value in the completion, specifically in Comp, CompCMO and CompPersist transactions, is ignored and the cache state remains unchanged.

[Table 4-27](#) shows the permitted Dataless transaction completion, the encoding of the Resp field, and the meaning of the response.

Table 4-27 Permitted Dataless transaction completion and Resp field encodings

Response	Resp[2:0]	Description
Comp_I	0b000	The final state of the cache line must be I.
Comp_UC	0b010	The final state of the cache line can be UD, UC, UCE, SC, or I.
Comp_SC	0b001	The final state of the cache line can be SC or I.
Comp_UD_PD	0b110	The final state of the cache line must be UD or SD. Responsibility for a Dirty cache line is being passed.

In a response with an error indication, the cache state is permitted to be any value, including reserved values. See [Errors and transaction structure on page 9-344](#). See [Combined Immediate Write and CMO on page 2-62](#) for CompCMO and CompPersist. See [Independent Stash request on page 7-307](#) for CompStashDone.

Write and Atomic transaction completion

A Write and AtomicStore completion is sent on the CRSP channel and uses the Comp or CompDBIDResp opcode.

No cache state information, or responsibility for a Dirty cache line, is communicated using the Write transaction completion. The Resp field of a Comp or CompDBIDResp response must be set to zero for a Write transaction completion. All cache state information and responsibility for a Dirty cache line are communicated with the WriteData. See [WriteData response](#).

The permitted Write transaction completion responses are:

Comp	Used when the completion response is separate from the DBIDResp or DBIDRespOrd response.
CompDBIDResp	Used when the completion response is combined with the DBIDResp or DBIDRespOrd response. All CopyBack requests must use the CompDBIDResp completion response. Immediate writes and AtomicStore, can either send Comp and DBIDResp or DBIDRespOrd responses separately or can opportunistically combine the two responses and send CompDBIDResp if both are ready to be sent to the Requester.

Miscellaneous transaction completion

A Comp response, with the Resp field set to zero, is always used for DVM transaction completion.

4.5.2 WriteData response

The WriteData response is part of Write request and DVMOp transactions. The Requester sends WriteData to the Completer after receiving a guarantee that a buffer is available to accept the data. Buffer availability is signaled through a DBIDResp or DBIDRespOrd response sent from the Completer.

The WriteData response is sent on the WDAT channel and uses the following opcodes.

CopyBackWriteData, CBWrData

Used for WriteBack, WriteClean, WriteEvictFull, and WriteEvictOrEvict, and CopyBack Combined Write transactions. Transfers coherent data from the cache at the Requester to the interconnect. Includes an indication of the cache line state prior to sending the WriteData response.

NonCopyBackWriteData, NCBWrData

Used for WriteUnique and WriteNoSnp, and Combined Immediate Write transactions. Also used for a DVMOp transaction. The cache state in the response must be I.

NonCopyBackWriteDataCompAck, NCBWrDataCompAck

Used for Immediate Write and Combined Write transactions. Combined NonCopyBackWrData and CompAck. The cache state in the response must be I.

WriteDataCancel

Used to inform the Completer that a Write request is canceled before write data is sent.

- A Request Node can send WriteDataCancel instead of NonCopyBackWrData in WriteNoSnpPtl, WriteUniquePtl, WriteUniquePtlStash, and corresponding Combined Write transactions.
- A Home Node can send WriteDataCancel instead of NonCopyBackWrData in WriteNoSnpFull, WriteNoSnpPtl, and corresponding Combined Write transactions to the Subordinate Node.
- Must not be used in Write requests to Device memory.
- All data packets originally intended to be transferred must be sent.
BE field value in the WriteDataCancel message must be set to all zeroes.

- Cache state in the response must be I.

The response includes the Resp field, which indicates the following:

- Cache state** Indicates the state of the cache line before sending the WriteData response. This state can differ from the state of the cache line when the original transaction request was sent if a snoop request, to the same address, is received by the Requester after sending the original transaction request, but before sending the corresponding WriteData response.
- Pass Dirty** Indicates if the responsibility for updating memory is passed by the Requester. The assertion of the Pass Dirty bit is shown by _PD in the response name.

Table 4-28 shows the permitted WriteData responses, the Opcode and Resp field encodings, and the meaning of the response.

Table 4-28 Permitted WriteData responses and Opcode and Resp field encodings

Response	DAT Opcode	Resp[2:0]	Description
CopyBackWrData_I	0x2	0b000	Indicates a CopyBack request has been canceled. The data in the response must be zero and all BE must be deasserted. The cache state in the response is imprecise and must be ignored.
CopyBackWrData_UC	0x2	0b010	Data corresponding to a CopyBack request. Cache line state when data was sent is UC.
CopyBackWrData_SC	0x2	0b001	Data corresponding to a CopyBack request. Cache line state when data was sent is SC.
CopyBackWrData_UD_PD	0x2	0b110	Data corresponding to a CopyBack request. Cache line state when data was sent is UD or UDP. Responsibility for updating the memory is passed.
CopyBackWrData_SD_PD	0x2	0b111	Data corresponding to a CopyBack request. Cache line state when data was sent is SD. Responsibility for updating the memory is passed.
NonCopyBackWrData	0x3	0b000	Data corresponding to an Immediate Write request.
NCBWrDataCompAck	0xC	0b000	Data corresponding to an Immediate Write request and combined CompAck to indicate that the transaction has completed.
WriteDataCancel	0x7	0b000	Indicates an Immediate Write request has been canceled. The data in the response must be zero and all BE must be deasserted.

———— **Note** ————

The cache line state at the Requester after the Write transaction has completed is not determined from the cache state information in the WriteData response. It can be determined if the cache line remains Valid or not after the transaction by the opcode of the transaction:

- A WriteBack or WriteEvictFull transaction must be in I state.

- A WriteClean transaction can remain allocated and be in a Clean state.
-

4.5.3 Snoop response

A Snoop transaction includes a Snoop response. A Snoop response can be with or without data. The forms of Snoop response are:

Snoop response without data

- This Snoop response is used when no data transfer is required.
- It is sent on the SRSP channel and uses the SnpResp opcode.
- It can include a DataPull request for stash snoops.
- Snoop response without data is always used for the response to a SnpDVMOp transaction.

Snoop response without data to Home and DCT

- This Snoop response is used when the Snoopee sends Data to the Requester and a data transfer to the Home is not required.
- It is sent on the SRSP channel and uses the SnpRespFwdded opcode.

Snoop response with data

- This Snoop response is used when a full cache line of data is transferred to Home.
- It is sent on the WDAT channel and uses the SnpRespData opcode.
- It can include a DataPull request for stash snoops.

Snoop response with partial data

- This Snoop response is used when a partial cache line of data is transferred to the Home.
- It is sent on the WDAT channel and uses the SnpRespDataPtl opcode.
- It can include a DataPull request for stash snoops.
- It is sent when the combination of the Snoop request and cache line state is:
 - Any Snoop request except SnpMakeInvalid, and the cache line state is UDP.

Snoop response with data to Home and DCT

- This Snoop response is used when the Snoopee sends Data to the Requester and a data transfer to the Home is also required.
- It is sent on the DAT channel and uses the SnpRespDataFwdded opcode.

The Snoop response includes the Resp field, which indicates the following:

Cache state The final state of the cache line at the snooped node after sending the Snoop response.

Pass Dirty Indicates that the responsibility for updating memory is passed to the Requester or ICN.
Pass Dirty must only be asserted for a Snoop response with data. The assertion of the Pass Dirty bit is shown by _PD in the response name.

The Snoop response also includes the FwdState field that is applicable in Snoop responses with DCT and indicates the cache state and pass dirty value in the CompData response sent to the Requester.

These attributes convey sufficient information for the interconnect to determine the appropriate response to the initial Requester, and to determine if data must be written back to memory. It is also sufficient to support snoop filter or directory maintenance in the interconnect.

See [Snoop requests on page 12-391](#) for details on Snoop responses and MTE interaction.

Note

The Snoop response cache state information provides the state of the cache line after the Snoop response is sent. This is different from:

- A WriteData response, where the cache state information provides the state of the cache line at the point the write data is sent.

- A read data response, where the cache state information indicates the permitted state of the cache line after the transaction completes.

Table 4-29 shows the permitted Non-forward type snoop responses without data, the RSP Opcode and Resp field encodings, and the meaning of the response.

Table 4-29 Permitted Non-forward type snoop responses without data

Response	RSP Opcode	Resp[2:0]	Description
SnpResp_I	0x1	0b000	Snoop response without data. Cache line state is I.
SnpResp_SC	0x1	0b001	Snoop response without data. Cache line state is SC, or I.
SnpResp_UC	0x1	0b010	Snoop response without data. Cache line state is UC, UCE, SC, or I.
SnpResp_UD	0x1	0b010	Snoop response without data. Cache line state is UD.
SnpResp_SD	0x1	0b011	Snoop response without data. Cache line state is SD.

Table 4-30 shows the permitted Forward type snoop responses without data, the RSP Opcode, Resp, and FwdState field encodings, and the meaning of the response.

Table 4-30 Permitted Forward type snoop responses without data

Response	RSP Opcode	Resp[2:0]	FwdState[2:0]	Description
SnpResp_I_Fwded_I	0x9	0b000	0b000	Snoop response without data. Cache line state is I. Copy of data forwarded to the Requester. Forward State is I.
SnpResp_I_Fwded_SC	0x9	0b000	0b001	Snoop response without data. Cache line state is I. Copy of data forwarded to the Requester. Forward State is SC.
SnpResp_I_Fwded_UC	0x9	0b000	0b010	Snoop response without data. Cache line state is I. Copy of data forwarded to the Requester. Forward State is UC.
SnpResp_I_Fwded_UD_PD	0x9	0b000	0b110	Snoop response without data. Cache line state is I. Copy of data forwarded to the Requester. Forward State is UD. Responsibility for updating the memory is passed.

Table 4-30 Permitted Forward type snoop responses without data (continued)

Response	RSP Opcode	Resp[2:0]	FwdState[2:0]	Description
SnpResp_I_Fwded_SD_PD	0x9	0b000	0b111	Snoop response without data. Cache line state is I. Copy of data forwarded to the Requester. Forward State is SD. Responsibility for updating the memory is passed.
SnpResp_SC_Fwded_I	0x9	0b001	0b000	Snoop response without data. Cache line state is SC. Copy of data forwarded to the Requester. Forward State is I.
SnpResp_SC_Fwded_SC	0x9	0b001	0b001	Snoop response without data. Cache line state is SC. Copy of data forwarded to the Requester. Forward State is SC.
SnpResp_SC_Fwded_SD_PD	0x9	0b001	0b111	Snoop response without data. Cache line state is SC. Copy of data forwarded to the Requester. Forward State is SD. Responsibility for updating the memory is passed.
SnpResp_UC_Fwded_I SnpResp_UD_Fwded_I	0x9	0b010	0b000	Snoop response without data. Cache line state is UC or UD. Copy of data forwarded to the Requester. Forward State is I. <div style="text-align: center;"> Note </div> A single encoding is used to indicate that the cache line is unique. This encoding is used for UC and UD.
SnpResp_SD_Fwded_I	0x9	0b011	0b000	Snoop response without data. Cache line state is SD. Copy of data forwarded to the Requester. Forward State is I.
SnpResp_SD_Fwded_SC	0x9	0b011	0b001	Snoop response without data. Cache line state is SD. Copy of data forwarded to the Requester. Forward State is SC.

Table 4-31 shows the permitted Non-forward type snoop responses with data, the DAT Opcode and Resp field encodings, and the meaning of the response.

Table 4-31 Permitted Non-forward type snoop responses with data

Response	DAT Opcode	Resp[2:0]	Description
SnpRespData_I	0x1	0b000	Snoop response with data. Cache line state is I.
SnpRespData_UC SnpRespData_UD	0x1	0b010	Snoop response with data. Cache line state is UC or UD. <div style="text-align: center;"> Note </div> A single encoding is used to indicate that the cache line is unique. This encoding is used for UC and UD.
SnpRespData_SC	0x1	0b001	Snoop response with data. Cache line state is SC.
SnpRespData_SD	0x1	0b011	Snoop response with data. Cache line state is SD.
SnpRespData_I_PD	0x1	0b100	Snoop response with data. Cache line state is I. Responsibility for updating the memory is passed to the Home.
SnpRespData_UC_PD	0x1	0b110	Snoop response with data. Cache line state is UC. Responsibility for updating the memory is passed to the Home.
SnpRespData_SC_PD	0x1	0b101	Snoop response with data. Cache line state is SC. Responsibility for updating the memory is passed to the Home.
SnpRespDataPtl_I_PD	0x5	0b100	Snoop response with partial data. Cache line state is I. Responsibility for updating the memory is passed to the Home.
SnpRespDataPtl_UD	0x5	0b010	Snoop response with partial data. Cache line state is UDP.

Table 4-32 shows the permitted Forward type snoop responses with data, the DAT Opcode, Resp, and FwdState field encodings, and the meaning of the response.

Table 4-32 Permitted Forward type snoop responses with data

Response	DAT Opcode	Resp[2:0]	FwdState[2:0]	Description
SnpRespData_I_Fwded_SC	0x6	0b000	0b001	Snoop response with data. Cache line state is I. Copy of data forwarded to the Requester. Forward State is SC.
SnpRespData_I_Fwded_SD_PD	0x6	0b000	0b111	Snoop response with data. Cache line state is I. Copy of data forwarded to the Requester. Forward State is SD. Responsibility of updating the memory is passed to the Requester.
SnpRespData_SC_Fwded_SC	0x6	0b001	0b001	Snoop response with data. Cache line state is SC. Copy of data forwarded to the Requester. Forward State is SC.
SnpRespData_SC_Fwded_SD_PD	0x6	0b001	0b111	Snoop response with data. Cache line state is SC. Copy of data forwarded to the Requester. Forward State is SD. Responsibility for updating the memory is passed to the Requester.
SnpRespData_SD_Fwded_SC	0x6	0b011	0b001	Snoop response with data. Cache line state is SD. Copy of data forwarded to the Requester. Forward State is SC.
SnpRespData_I_PD_Fwded_I	0x6	0b100	0b000	Snoop response with data. Cache line state is I. Responsibility for updating the memory is passed to the Home. Copy of data forwarded to the Requester. Forward State is I.

Table 4-32 Permitted Forward type snoop responses with data (continued)

Response	DAT Opcode	Resp[2:0]	FwdState[2:0]	Description
SnpRespData_I_PD_Fwded_SC	0x6	0b100	0b001	Snoop response with data. Cache line state is I. Responsibility for updating the memory is passed to the Home. Copy of data forwarded to the Requester. Forward State is SC.
SnpRespData_SC_PD_Fwded_I	0x6	0b101	0b000	Snoop response with data. Cache line state is SC. Responsibility for updating the memory is passed to the Home. Copy of data forwarded to the Requester. Forward State is I.
SnpRespData_SC_PD_Fwded_SC	0x6	0b101	0b001	Snoop response with data. Cache line state is SC. Responsibility for updating the memory is passed to the Home. Copy of data forwarded to the Requester. Forward State is SC.

The cache line state associated with a Snoop response with data must be a legal value, even if the RespErr field indicates there is a Data Error. A Snoop response with data is not permitted to have a Non-data Error. See [Snoop transactions on page 9-353](#).

In responses to stash snoops, the Snoopee can send a Read request combined with the Snoop response (SnpResp_X_Read), by setting the DataPull bit. The permitted Snoop responses with Data Pull are:

- For SnpUniqueStash:
 - SnpResp_I_Read
 - SnpRespData_I_Read
 - SnpRespData_I_PD_Read
 - SnpRespDataPtl_I_PD_Read
- For SnpMakeInvalidStash:
 - SnpResp_I_Read
- For SnpStashUnique:
 - SnpResp_I_Read
 - SnpResp_UC_Read
 - SnpResp_SC_Read
 - SnpResp_SD_Read
- For SnpStashShared:
 - SnpResp_I_Read
 - SnpResp_UC_Read

4.5.4 Miscellaneous response

This section describes responses that cannot be classified as a completion, WriteData, or Snoop response.

For all responses in this section the Resp and RespErr fields have no meaning and must be set to zero.

The miscellaneous responses are:

CompAck

Sent by the Requester on receipt of the completion response. Used by Read, Dataless, WriteNoSnp, WriteEvictOrEvict, and WriteUnique transactions.

See [Transaction structure on page 2-46](#).

RetryAck

Sent by a Completer to a Requester if the request is not accepted at the Completer due to lack of appropriate resources. Response is permitted for any request transaction except PCrdReturn or PrefetchTgt.

See [Retry on page 2-83](#).

PCrdGrant

Grants a Protocol Credit. A subsequent request, sent using the Protocol Credit, is guaranteed to be accepted by the target.

See [Retry on page 2-83](#).

ReadReceipt

- Sent for a request that has an ordering requirement with respect to other ordered requests from the same Requester.
- Sent by a Subordinate Node to indicate it has accepted a Read request and will not send a RetryAck response.
- See [Ordering requirements on page 2-126](#) for how ReadReceipt is used in an ordered request.
- Applies to ReadNoSnp, ReadNoSnpSep, and ReadOnce* request transactions.

See [Read transactions on page 2-47](#).

DBIDResp

- Response sent to signal to the Requester that resources are available to accept the WriteData response.
- DBIDResp response also indicates that the Completer provides certain transaction ordering guarantees. See [Transaction ordering on page 2-125](#).
- Applies to Write, Combined Write, DVMOOp, and Atomic request transactions.
- The response is permitted from Home Node to Request Node and Subordinate Node to both a Home Node and Request Node.

See [Transaction structure on page 2-46](#).

DBIDRespOrd

- Response sent to signal to the Requester that resources are available to accept the WriteData response.
- DBIDRespOrd response also indicates that the Completer provides certain transaction ordering guarantees. See [Transaction ordering on page 2-125](#).
- Applies to Write, Combined Write, and Atomic request transactions.
- DBIDRespOrd is not permitted in DVM transactions.
- The response is permitted from Home Node to Request Node only.

See [Transaction ordering on page 2-125](#).

Persist

Sent by a Completer for CleanSharedPersistSep transaction to indicate that any data written earlier to the same memory location is made persistent.

See [Combined Immediate Write and Persist CMO on page 2-66](#) and [Combined CopyBack Write and CMO on page 2-72](#).

StashDone

Sent by a Completer for StashOnceSep to signal the ordering of the request at the Completer.

See [Independent Stash request on page 7-307](#).

TagMatch

Sent by the Completer for a Write transaction with TagOp of *Match* to signal the completion of the Tag Match operation.

See [Tag Match on page 12-394](#).

4.6 Silent cache state transitions

A cache can change state due to an internal event without notifying the rest of the system.

The legal silent cache state transitions are shown in [Table 4-33](#). In some cases it is possible, but not required, to issue a transaction to indicate that the transition has occurred. If such a transaction is issued, then the cache state transition is visible to the interconnect and is not classified as a silent transition.

The RN-F action described in [Table 4-33](#) as *Local sharing*, describes the case where an RN-F specifies a Unique cache line as Shared, effectively disregarding the fact that the cache line remains Unique to the RN-F. For example, this can happen when the RN-F contains multiple internal agents and the cache line becomes shared between them.

For silent cache state transitions:

- Cache eviction and Local sharing transitions can occur at any point and are IMPLEMENTATION DEFINED.
- Store and Cache Invalidate transitions can only occur as the result a deliberate action, which in the case of a core is caused by the execution of a particular program instruction.

The Notes column in [Table 4-33](#) indicates how a silent cache transition can be made non-silent or visible at the interface.

Table 4-33 Legal silent cache state transitions

RN-F action	RN-F Cache state		Notes
	Present	Next	
Cache eviction	UC	I	Can use Evict, WriteEvictFull, or WriteEvictOrEvict transaction.
	UCE	I	Can use Evict transaction.
	SC	I	Can use Evict transaction.
Local sharing	UC	SC	-
	UD	SD	-
Store	UC	UD	Full or partial cache line store
	UCE	UDP	Partial cache line store
	UCE	UD	Full cache line store
	UDP	UD	Store that fills the cache line
Cache Invalidate	UD	I	Can use Evict transaction.
	UDP	I	Can use Evict transaction.

A cache state change from UC to UCE is not permitted.

————— **Note** —————

Sequences of silent transitions can also occur. Any silent transition that results in the cache line being in UD, UDP, or SC state can undergo a further silent transition.

4.7 Cache state transitions at a Requester

This section specifies the cache state transitions and completion responses for the following request transactions:

- [Read request transactions](#)
- [Dataless request transactions on page 4-229](#)
- [Write request transactions on page 4-230](#)
- [Atomic transactions on page 4-231](#)
- [Other request transactions on page 4-231](#)

4.7.1 Read request transactions

[Table 4-34](#) shows the cache state transitions at the Requester, and the completion responses, for Read request transactions except for the MakeReadUnique transaction.

For details of the permitted completion responses and cache state transitions at the Requester for the MakeReadUnique transaction, both Non-exclusive and Exclusive, see [MakeReadUnique transaction on page 4-224](#).

The cache state in the Data response to the Requester from the Subordinate Node is UC, that is, CompData_UC irrespective of the original request type. The Requester must ignore the cache state in the CompData response to ReadNoSnp, ReadOnce, ReadOnceCleanInvalid, and ReadOnceMakeInvalid and implicitly assume the cache state value to be I.

————— Note —————

In a non-DMT data transfer, where the CompData response is sent from the Subordinate to Home, the cache state in the response can be either I or UC. It is expected that typically the design of a Subordinate can be simplified by always using UC. Home then sends CompData to the Requester with the appropriate cache state value.

Table 4-34 Cache state transitions at the Requester for Read request transactions

Request type	Cache state		Final	Comp response	Separate responses
	Initial				
	Expected	Others permitted			
ReadNoSnp	I	-	I	CompData_UC, CompData_I	RespSepData + DataSepResp_UC
ReadOnce	I, UCE ^a	-	I	CompData_UC, CompData_I	RespSepData + DataSepResp_UC
ReadOnceCleanInvalid	I, UCE ^a	-	I	CompData_UC, CompData_I	RespSepData + DataSepResp_UC
ReadOnceMakeInvalid	I, UCE ^a	-	I	CompData_UC, CompData_I	RespSepData + DataSepResp_UC

Table 4-34 Cache state transitions at the Requester for Read request transactions (continued)

Request type	Cache state		Final	Comp response	Separate responses
	Initial				
	Expected	Others permitted			
ReadClean TagOp = <i>Transfer</i>	I	-	SC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
	UC, UCE		UC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
	UD, UDP	-	UD	CompData_SC	RespSepData + DataSepResp_SC
			UD	CompData_UC	RespSepData + DataSepResp_UC
	SC	-	SC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
	SD ^b	-	SD	CompData_SC	RespSepData + DataSepResp_SC
			UD	CompData_UC	RespSepData + DataSepResp_UC
ReadClean TagOp != <i>Transfer</i>	I	-	SC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
	UCE	-	UC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
ReadNotSharedDirty	I, UCE ^a	-	SC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
			UD	CompData_UD_PD	RespSepData + DataSepResp_UD_PD

Table 4-34 Cache state transitions at the Requester for Read request transactions (continued)

Request type	Cache state		Final	Comp response	Separate responses
	Initial				
	Expected	Others permitted			
ReadShared	I, UCE ^a	-	SC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
			SD	CompData_SD_PD	-
			UD	CompData_UD_PD	RespSepData + DataSepResp_UD_PD
ReadUnique	I, SC	UC, UCE	UC	CompData_UC	RespSepData + DataSepResp_UC
			UD	CompData_UD_PD	RespSepData + DataSepResp_UD_PD
	SD	UD, UDP ^c	UD	CompData_UC	RespSepData + DataSepResp_UC,
				CompData_UD_PD	RespSepData + DataSepResp_UD_PD
ReadPreferUnique	I, SC	-	SC	CompData_SC	RespSepData + DataSepResp_SC
			UC	CompData_UC	RespSepData + DataSepResp_UC
			UD	CompData_UD_PD	RespSepData + DataSepResp_UD_PD
	SD ^b	-	SD	CompData_SC	RespSepData + DataSepResp_SC
			UD	CompData_UC	RespSepData + DataSepResp_UC,
			CompData_UD_PD	RespSepData + DataSepResp_UD_PD	
MakeReadUnique	See Table 4-37 on page 4-227 and Table 4-38 on page 4-228.				

- For ReadOnce*, ReadNotSharedDirty and ReadShared transactions the Requester with an initial state of UCE must not upgrade the cache line to UDP nor UD while the request is outstanding.
- A Requester in initial state of SD that receives a CompData_SC or DataSepResp_SC response must stay in SD state. Similarly, a Home that uses a Snoop filter to track the cached state at the Requester, must not downgrade the state of the cache line in the snoop filter based on the state in the response to the Requester.
- Data received from memory must be dropped if the cache state is UD or SD, or merged if the cache state is UDP. Data received from memory must be the same as the cached data when the cache state is SC or UC.

MakeReadUnique transaction

This section describes the permitted responses and the cache state transitions at the Requester, for the MakeReadUnique and MakeReadUnique(Excl) transactions. The additional MakeReadUnique(Excl) behavioral requirements are described in [MakeReadUnique\(Excl\)](#) on page 6-298.

Permitted responses

Table 4-35 shows the permitted responses in a MakeReadUnique transaction. Table 4-36 on page 4-225 shows the additional responses that are permitted only when the Exclusive bit in the request is set to one. This attribute is indicated by adding the suffix (Excl) to the request.

Some key features of the permitted responses are:

- A response without data, Comp_UD_PD, indicates that the Requester is being passed responsibility for a Dirty cache line.
This can occur when the Requester holds a SharedClean copy of the cache line and another agent holds a SharedDirty copy. The Home invalidates the SharedDirty copy, for example using a SnpMakeInvalid transaction, and then passes the responsibility for the Dirty cache line to the Requester that issued the MakeReadUnique transaction.
- A response with a cache state of SC is only permitted in response to an Exclusive version of MakeReadUnique.
Comp_SC, an example of a response with a cache state of SC, is sent when the Home determines that the Exclusive Store has failed but the snoop filter, or response to a SnpQuery snoop to the Requester, indicates that the Requester still holds a copy of the cache line while there is another shared copy in the system.

————— Note —————

The above situation can occur with a non-full address PoC exclusive monitor. The monitor bit for an LP can be reset by another LP performing an Exclusive store to a different address location. This store to a different address does not invalidate the cached copy of the address location being used for Exclusive access by the first Requester.

Table 4-35 shows the permitted responses in both the non-Exclusive and Exclusive MakeReadUnique transaction.

Table 4-35 Permitted responses in the MakeReadUnique transaction

Response Received	Description
Comp_UC	Requester retains its copy of the cache line. All other cached copies have been invalidated. Cache line might be Clean or Dirty at the Requester.
Comp_UD_PD	Requester retains its copy of the cache line. Dirty copy of the cache line held elsewhere has been invalidated. Cache line must become Dirty at the Requester.
CompData_UC	Requester lost the cache line while the transaction was in progress. Clean copy of the cache line is given to the Requester. Combined data and completion responses are given.

Table 4-35 Permitted responses in the MakeReadUnique transaction (continued)

Response Received	Description
CompData_UD_PD	Requester lost the cache line while the transaction was in progress. Dirty copy of the cache line is given to the Requester. Combined data and completion responses are given.
RespSepData, DataSepResp_UC	Requester lost the cache line while the transaction was in progress. Clean copy of the cache line is given to the Requester. Separate data and completion responses are given.
RespSepData, DataSepResp_UD_PD	Requester lost the cache line while the transaction was in progress. Dirty copy of the cache line is given to the Requester. Separate data and completion responses given by Home.

Table 4-36 shows the additional permitted responses in the Exclusive MakeReadUnique transaction.

Table 4-36 Additional permitted responses in the MakeReadUnique (Excl) transaction

Response received	Description
Comp_SC	Global Exclusive check fails. Shared cached copy exists in another cache. Requester retains its copy of the cache line.
CompData_SC	Global Exclusive check fails. Shared cached copy exists in another cache. Requester might have lost its copy of the cache line.
RespSepData DataSepResp_SC	Global Exclusive check fails. Shared cached copy exists in another cache. Requester might have lost its copy of the cache line.

Expected snoops

The use of snoops by the Home to invalidate a cache line at the Snoopee in response to a non-Exclusive MakeReadUnique, or an Exclusive MakeReadUnique that passes an Exclusive check, are as follows:

- The Home is expected to use a SnpCleanInvalid snoop:
 - The Home is permitted to use SnpUnique instead of SnpCleanInvalid.
 - The Home is permitted to use SnpUniqueFwd if it determines that the Requester has lost the cached copy of the cache line.
 - The Home is also permitted to use SnpMakeInvalid instead of SnpCleanInvalid if it determines that the Snoopee does not have a Dirty copy of the cache line.

See [Home behavior on page 6-298](#) for the types of snoops the Home is expected and permitted to use when an Exclusive MakeReadUnique request fails the Exclusive check.

Cache line state transitions

The final state of the cache line after a MakeReadUnique transaction depends on the state of the cache line immediately before the transaction response is received. This can be different from the state of the cache line at the point the transaction is issued.

For MakeReadUnique, the Requester must keep a copy of the cache line unless it receives an invalidating snoop.

- Invalidating snoops are SnpUnique, SnpUniqueFwd, SnpCleanInvalid, SnpMakeInvalid, SnpUniqueStash, and SnpMakeInvalidStash.
- The Requester is permitted to treat SnpPreferUnique and SnpPreferUniqueFwd as either invalidating or non-invalidating. The Home can determine how these snoops are treated by the Snoopee by inspecting the Snoop response.
- All other snoops are non-invalidating and the Requester is required to keep a copy of the cache line.

If the Home does not have an SF, or the SF is imprecise, and the Home cannot determine if the Requester still has a copy of the cache line at the point that the transaction completes, then the Home must assume the cache line is lost at the Requester and provide data with the response.

A Requester that receives a response with data, while still holding the line in SD state, must use its own copy of the cache line, rather than the copy returned with the response.

————— **Note** —————

A Requester that receives a response with data, while still holding the line in SD state implies there is no snoop filter present or that the snoop filter is imprecise. In this case, it is possible that the data returned with the response is Stale.

If the Requester is aware that there is no snoop filter, then it can use a CleanUnique transaction instead of MakeReadUnique to avoid an unnecessary memory read when the cache line is not cached at any other agent.

————— **Note** —————

Use of the CleanUnique transaction can avoid an unnecessary memory read in the absence of a snoop filter. The unnecessary memory read occurs when the cache line remains cached at the Requester, but a snoop filter is not present in the system or a SnpQuery snoop is not used and a cached copy is not available from another agent in the system. However, using a CleanUnique transaction will result in the Requester needing to issue another transaction in the case where the cache line is lost due to a snoop while the transaction is in progress.

[Table 4-35 on page 4-224](#) shows the state transitions and responses that are applicable to both non-Exclusive and Exclusive versions of MakeReadUnique. [Table 4-36 on page 4-225](#) shows the additional state transitions and responses that apply only to the Exclusive version of the request.

The response rules are:

- The cache state in the response to a non-Exclusive MakeReadUnique must be Unique.
- The cache state in the response to an Exclusive MakeReadUnique is permitted to be Unique or Shared.
- The cache state in the response to an Exclusive and to a Non-exclusive MakeReadUnique must not include Shared Dirty.
- For each permitted combined completion and data response, a corresponding response with separate completion and data is permitted.

[Table 4-37 on page 4-227](#) and [Table 4-38 on page 4-228](#) include columns for:

- The initial cache state.
- The cache state immediately before the transaction response is received.
- The final state for each of the possible response combinations.

The handling of a MakeReadUnique transaction at the Home depends on the availability or not of a precise Snoop Filter. [Table 4-37](#) and [Table 4-38 on page 4-228](#) also include the responses that are permitted with and without a precise Snoop Filter:

- The table column labeled: Snoop Filter - Precise, covers the cases when the precise state of the cache line at the Requester, at the response time, is known. The Home obtains the knowledge of precise state from a snoop filter, or by sending a SnpQuery snoop, or in some other IMPLEMENTATION DEFINED manner.
- The column labeled: Snoop Filter - Imprecise or Absent, covers the cases when the precise state of the cache line at the Requester, at the response time, is not known. This also includes the case when there is no snoop filter, or the Home might decide to ignore the available precise information, or not attempt to obtain the information.

[Table 4-37](#) and [Table 4-38 on page 4-228](#) use the following key:

Y Yes, permitted
- Not permitted

Table 4-37 Cache state transitions at the Requester for the MakeReadUnique request (non-Excl and Excl)

Cache State				Snoop Filter					
Initial	At time of Response	Home sent invalidating snoop	Final	Comp Resp	Precise	Imprecise or Absent	Notes		
SD	SD	No	UD	Comp_UC	Y	-	Returned data might be stale		
				CompData_UC	-	Y			
				RespSepData, DataSepResp_UC	-	Y			
SC, SD	SC	No	UC	Comp_UC	Y	-	Data in response is identical to the Requester copy		
				CompData_UC	-	Y			
				RespSepData, DataSepResp_UC	-	Y			
			UD	Comp_UD_PD	Y	-			
				CompData_UD_PD	-	Y			
				RespSepData, DataSepResp_UD_PD	-	Y			
			I	Yes	UC	CompData_UC		Y	Y
						RespSepData, DataSepResp_UC		Y	Y
					UD	CompData_UD_PD		Y	Y
RespSepData, DataSepResp_UD_PD	Y	Y							
I, UC, UD	Not permitted								

Table 4-38 Additional Cache state transitions at the Requester for the MakeReadUnique(Excl) request

Cache State				Snoop Filter		
Initial	At time of Response	Home sent invalidating snoop	Final	Comp Resp	Precise	Imprecise or Absent
SC, SD	SC	No	SC	Comp_SC	Y	-
	I	Yes	SC	CompData_SC	Y	Y
				RespSepData DataSepResp_SC	Y	Y
SD	SD	No	SD	Comp_SC	Y	-
				CompData_SC	-	Y
				RespSepData DataSepResp_SC	-	Y

See [MakeReadUnique\(Excl\)](#) on page 6-298 for the additional MakeReadUnique(Excl) behavioral requirements.

4.7.2 Dataless request transactions

Table 4-39 shows the cache state transitions at the Requester, and the completion responses, for Dataless request transactions.

Table 4-39 Cache state transitions at the Requester for Dataless request transactions

	Cache state			
Request type	Initial		Final	Comp Response
	Expected	Others permitted		
CleanUnique	I	UC, UCE	UCE	Comp_UC
	SC	UC	UC	Comp_UC
	SD	UD	UD	Comp_UC
MakeUnique	I, SC, SD	UC, UCE	UD	Comp_UC
Evict	I	-	I	Comp_I
StashOnceUnique	I	-	I	Comp
StashOnceSepUnique	I	-	I	Comp + StashDone or CompStashDone
StashOnceShared	I	-	I	Comp
StashOnceSepShared	I	-	I	Comp + StashDone or CompStashDone
CleanShared CleanSharedPersist	I, SC, UC	-	No Change	Comp_UC
				Comp_SC
				Comp_I
CleanSharedPersistSep	I, SC, UC	-	No Change	Comp_UC + Persist or CompPersist_UC
				Comp_SC + Persist or CompPersist_SC
				Comp_I + Persist or CompPersist_I
CleanInvalid	I	-	I	Comp_I
MakeInvalid	I	-	I	Comp_I

Before a CleanInvalid, MakeInvalid, or Evict transaction it is permitted for the cache state to be UC, UCE or SC. However, it is required that the cache state transitions to the I state before the transaction is issued. Therefore, Table 4-39 shows I state as the only initial state.

4.7.3 Write request transactions

Table 4-40 shows the cache state transitions at the Requester, the WriteData response, and the combined or separate completion and DBIDResp response for Write and corresponding Combined Write request transactions. Combined Write request transactions are not listed in Table 4-40. See [Combined Write requests on page 4-192](#).

Table 4-40 Requester cache state transitions for Write request transactions

Request Type	Cache state at Requester			Comp response	WriteData response
	Initial	Before WriteData response ^a	Final		
WriteNoSnpPtl	I	-	I	DBIDResp* + Comp or CompDBIDResp	NCBWrData or NCBWrDataCompAck or WriteDataCancel
WriteNoSnpFull	I	-	I	DBIDResp* + Comp or CompDBIDResp	NCBWrData or NCBWrDataCompAck
WriteNoSnpZero	I	-	I	DBIDResp* + Comp or CompDBIDResp	None
WriteUniquePtl WriteUniquePtlStash	I	I	I	DBIDResp* + Comp or CompDBIDResp	NCBWrData or WriteDataCancel or NCBWrDataCompAck
WriteUniqueZero	I	I	I	DBIDResp* + Comp or CompDBIDResp	None
WriteUniqueFull WriteUniqueFullStash	I	I	I	DBIDResp* + Comp or CompDBIDResp	NCBWrData or NCBWrDataCompAck
WriteBackFull	UD	UD	I	CompDBIDResp	CBWrData_UD_PD
		UC	I	CompDBIDResp	CBWrData_UC
	UD, SD	SD	I	CompDBIDResp	CBWrData_SD_PD
		SC	I	CompDBIDResp	CBWrData_SC
		I	I	CompDBIDResp	CBWrData_I
WriteBackPtl	UDP	UDP	I	CompDBIDResp	CBWrData_UD_PD
		I	I	CompDBIDResp	CBWrData_I
WriteCleanFull	UD	UD	UC ^b	CompDBIDResp	CBWrData_UD_PD
		UC	UC ^b	CompDBIDResp	CBWrData_UC
				CompDBIDResp	CBWrData_I
	UD, SD	SD	SC	CompDBIDResp	CBWrData_SD_PD
		SC	SC	CompDBIDResp	CBWrData_SC
				CompDBIDResp	CBWrData_I
		I	I	CompDBIDResp	CBWrData_I

Table 4-40 Requester cache state transitions for Write request transactions (continued)

Request Type	Cache state at Requester			Comp response	WriteData response
	Initial	Before WriteData response ^a	Final		
WriteEvictFull	UC	UC	I	CompDBIDResp	CBWrData_UC
		SC	I	CompDBIDResp	CBWrData_SC
		I	I	CompDBIDResp	CBWrData_I
WriteEvictOrEvict	UC	UC ^c	I	CompDBIDResp	CBWrData_UC
			I	Comp ^d	None
	UC, SC	SC	I	CompDBIDResp	CBWrData_SC
			I	Comp ^d	None
		I	I	CompDBIDResp	CBWrData_I
			I	Comp ^d	None

- a. A snoop might be received while a write is pending and results in a cache line state change before the WriteData response.
b. After completion of a WriteClean transaction, it is possible for the cache line in a Unique state to immediately transition to a Dirty state.
c. Once the request is sent the Requester is permitted to keep the cache state in UC but must not modify the cache line.
d. Comp is sent if the Home decides not to request data.

4.7.4 Atomic transactions

Table 4-41 shows the cache state transitions at the Requester, and the completion and response for Atomic transactions.

Table 4-41 Requester cache state transitions for Atomic request transactions

Atomic request	Cache state		Final	Comp response	WriteData response
	Initial				
	Expected	Others permitted			
AtomicStore	I, SC UCE, SD	UC, UD, UDP	I	DBIDResp* + Comp_I or CompDBIDResp	NCBWrData
AtomicLoad	I, SC UCE, SD	UC, UD, UDP	I	DBIDResp* + CompData_I	NCBWrData
AtomicSwap	I, SC UCE, SD	UC, UD, UDP	I	DBIDResp* + CompData_I	NCBWrData
AtomicCompare	I, SC UCE, SD	UC, UD, UDP	I	DBIDResp* + CompData_I	NCBWrData

4.7.5 Other request transactions

DVMOp and PrefetchTgt requests do not have any cache state transitions associated with them.

4.8 Cache state transitions at a Snoopee

This section specifies the cache state transitions and completion responses for the following Snoop transactions:

- [Non-Forwarding and Non-stash Snoop transactions](#)
- [Stash snoop transactions on page 4-238](#)
- [Forwarding Snoop transactions on page 4-240](#)

A Snoopee, an RN-F that receives a snoop, performs two actions. One action is a state change of the cached line and the second action is sending a response message either to the Home, or to both the Home and the Requester.

The cache state change depends on the snoop type, the initial state of the cache line and the value of DoNotGoToSD in the snoop. See [Do not transition to SD on page 4-252](#).

The Snoopee must send a response to Home either with Data or without Data. If for Forwarding snoops, the Snoopee can also forward a Data response to the Requester.

The type of response sent is determined by the snoop type, initial cache state, cache state change, and the value of RetToSrc. See [Returning Data with Snoop response on page 4-251](#).

4.8.1 Non-Forwarding and Non-stash Snoop transactions

The Non-forwarding and Non-stash Snoop transactions are:

- [SnpOnce](#)
- [SnpClean, SnpShared, SnpNotSharedDirty, and SnpPreferUnique on page 4-234](#)
- [SnpUnique and SnpPreferUnique on page 4-235](#)
- [SnpCleanShared, SnpCleanInvalid, and SnpMakeInvalid on page 4-236](#)
- [SnpQuery on page 4-237](#)

SnpOnce

[Table 4-42 on page 4-233](#) shows for SnpOnce, the initial, expected final, and other permitted final cache states at the snooped Requester, the RetToSrc field value, and the valid completion response from a snooped RN-F.

Table 4-42 Cache state transitions, RetToSrc value, and valid completion responses

Snoop request type	Initial cache state	Final cache state		RetToSrc ^a	Snoop response
		Expected	Others permitted		
SnpOnce	I	I	-	X	SnpResp_I
	UC	UC	I, SC	X	SnpResp_UC
					SnpRespData_UC
		SC	I	X	SnpResp_SC
					SnpRespData_SC
	UCE	I	-	X	SnpResp_I
					SnpRespData_I
		UCE	I	X	SnpResp_UC
		I	-	X	SnpResp_I
	UD	UD	SD	X	SnpRespData_UD
		SD	-	X	SnpRespData_SD
		SC	I	X	SnpRespData_SC_PD
		I	-	X	SnpRespData_I_PD
	UDP	I	-	X	SnpRespDataPtl_I_PD
		UDP	-	X	SnpRespDataPtl_UD
	SC	SC	I	0	SnpResp_SC
				1	SnpRespData_SC
		I	-	0	SnpResp_I
				1	SnpRespData_I
	SD	SD	-	X	SnpRespData_SD
		SC	I	X	SnpRespData_SC_PD
		I	-	X	SnpRespData_I_PD

a. X indicates that the protocol requirements apply for both states of RetToSrc.

SnpClean, SnpShared, SnpNotSharedDirty, and SnpPreferUnique

Table 4-43 shows for SnpClean, SnpShared, SnpNotSharedDirty and SnpPreferUnique the initial, expected final, and other permitted final cache states at the snooped Requester, the RetToSrc field value, and the valid completion response from a snooped RN-F. Table 4-43 must be used to determine SnpPreferUnique cache state transitions when the Snoopee is in the middle of executing an Exclusive access sequence. A Snoopee that is not in the middle of executing an Exclusive access is permitted, but not expected, to use Table 4-43 to determine SnpPreferUnique cache state transitions.

See *SnpPreferUnique and SnpPreferUniqueFwd* on page 4-247 for constraints on determining when a Requester is in the middle of executing an exclusive sequence.

Table 4-43 Cache state transitions, RetToSrc value, and valid completion responses

Snoop request type	Initial cache state	Final cache state		RetToSrc ^a	Snoop response
		Expected	Others permitted		
SnpClean, SnpShared, SnpNotSharedDirty, SnpPreferUnique ^b	I	I	-	X	SnpResp_I
	UC	SC	I	X	SnpResp_SC
					SnpRespData_SC
		I	-	X	SnpResp_I
					SnpRespData_I
	UCE	I	-	X	SnpResp_I
	UD	SD ^c	-	X	SnpRespData_SD
					SnpRespData_SC_PD
		I	-	X	SnpRespData_I_PD
	UDP	I	-	X	SnpRespDataPtl_I_PD
	SC	SC	I	0	SnpResp_SC
				1	SnpRespData_SC
		I	-	0	SnpResp_I
				1	SnpRespData_I
	SD	SD ^c	-	X	SnpRespData_SD
				X	SnpRespData_SC_PD
		I	-	X	SnpRespData_I_PD

a. X indicates that the protocol requirements apply for both states of RetToSrc.

b. Applicable when the Snoopee is in the middle of executing an Exclusive sequence. Protocol compliant at any time. See also Table 4-44 on page 4-235.

c. This state transition is not permitted if DoNotGoToSD is set.

SnpUnique and SnpPreferUnique

Table 4-44 shows for SnpUnique and SnpPreferUnique the initial, expected final, and other permitted final cache states at the snooped Requester, the RetToSrc field value, and the valid completion response from a snooped RN-F for SnpUnique. Table 4-44 is expected to be used to determine SnpPreferUnique cache state transitions when the Snoopee is not in the middle of executing an Exclusive access sequence.

Table 4-44 Cache state transitions, RetToSrc value, and valid completion responses

Snoop request type	Initial cache state	Final cache state		RetToSrc ^a	Snoop response
		Expected	Others permitted		
SnpUnique, SnpPreferUnique ^b	I	I	-	X	SnpResp_I
	UC	I	-	X	SnpResp_I
					SnpRespData_I
	UCE	I	-	X	SnpResp_I
	UD	I	-	X	SnpRespData_I_PD
	UDP	I	-	X	SnpRespDataPtl_I_PD
	SC	I	-	0	SnpResp_I
				1	SnpRespData_I
	SD	I	-	X	SnpRespData_I_PD

- a. X indicates that the protocol requirements apply for both states of RetToSrc.
- b. Only applicable when the Snoopee is not in the middle of executing an Exclusive sequence.

SnpCleanShared, SnpCleanInvalid, and SnpMakeInvalid

Table 4-45 shows for SnpCleanShared, SnpCleanInvalid, and SnpMakeInvalid the initial, expected final, and other permitted final cache states at the snooped Requester, the RetToSrc field value, and the valid completion response from a snooped RN-F.

Table 4-45 Cache state transitions, RetToSrc value, and valid completion responses

Snoop request type	Initial cache state	Final cache state		RetToSrc	Snoop response
		Expected	Others permitted		
SnpCleanShared	I	I	-	0	SnpResp_I
	UC	UC	I, SC	0	SnpResp_UC
		SC	I	0	SnpResp_SC
		I	-	0	SnpResp_I
	UCE	I	-	0	SnpResp_I
	UD	UC	I, SC	0	SnpRespData_UC_PD
		SC	I	0	SnpRespData_SC_PD
		I	-	0	SnpRespData_I_PD
	UDP	I	-	0	SnpRespDataPtl_I_PD
	SC	SC	I	0	SnpResp_SC
		I	-	0	SnpResp_I
	SD	SC	I	0	SnpRespData_SC_PD
		I	-	0	SnpRespData_I_PD
SnpCleanInvalid	I	I	-	0	SnpResp_I
	UC	I	-	0	SnpResp_I
	UCE	I	-	0	SnpResp_I
	UD	I	-	0	SnpRespData_I_PD
	UDP	I	-	0	SnpRespDataPtl_I_PD
	SC	I	-	0	SnpResp_I
	SD	I	-	0	SnpRespData_I_PD
SnpMakeInvalid	I	I	-	0	SnpResp_I
	UC	I	-	0	SnpResp_I
	UCE	I	-	0	SnpResp_I
	UD	I	-	0	SnpResp_I
	UDP	I	-	0	SnpResp_I
	SC	I	-	0	SnpResp_I
	SD	I	-	0	SnpResp_I

SnpQuery

Table 4-46 shows for SnpQuery the initial, expected final, and other permitted final cache states at the snooped Requester, the RetToSrc field value, and the valid completion response from a snooped RN-F.

Table 4-46 Cache state transitions, RetToSrc value, and valid completion responses

Snoop request type	Initial cache state	Final cache state		RetToSrc	Snoop response
		Expected	Others permitted		
SnpQuery	I	I	-	0	SnpResp_I
	UC	UC	-	0	SnpResp_UC
	UCE	UCE	-	0	SnpResp_UC
	UD	UD	-	0	SnpResp_UD
	UDP	UDP	-	0	SnpResp_UD
	SC	SC	-	0	SnpResp_SC
	SD	SD	-	0	SnpResp_SD

4.8.2 Stash snoop transactions

The following sub-sections show the permitted responses for the Stash type snoops:

- [SnpUniqueStash and SnpMakeInvalidStash](#)
- [SnpStashUnique and SnpStashShared on page 4-239](#)

SnpUniqueStash and SnpMakeInvalidStash

The permitted responses to SnpUniqueStash and SnpMakeInvalidStash are the same as the responses to SnpUnique and SnpMakeInvalid respectively.

The RetToSrc bit value must not be set to 1 in SnpUniqueStash and SnpMakeInvalidStash.

Any Snoop response to SnpUniqueStash and SnpMakeInvalidStash can include a DataPull request. A DataPull request in a Snoop response to SnpUniqueStash and SnpMakeInvalidStash must be treated as a ReadUnique request.

[Table 4-47](#) shows the Snoopee cache state transitions and required Snoop responses. The Snoop responses do not include the DataPull options. DataPull is permitted with any Snoop response.

Table 4-47 Snoop response to SnpUniqueStash and SnpMakeInvalidStash

Snoop request type	Cache state			RetToSrc	Snoop response
	Initial	Final			
	Expected	Others permitted			
SnpUniqueStash	I	I	-	0	SnpResp_I
	UC	I	-	0	SnpRespData_I
					SnpResp_I
	UCE	I	-	0	SnpResp_I
	UD	I	-	0	SnpRespData_I_PD
	UDP	I	-	0	SnpRespDataPtl_I_PD
	SC	I	-	0	SnpResp_I
					SnpRespData_I
	SD	I	-	0	SnpRespData_I_PD
SnpMakeInvalidStash	Any	I	-	0	SnpResp_I

SnpStashUnique and SnpStashShared

For SnpStashUnique and SnpStashShared, the Snoopee must not change cache state.

The Snoopee is permitted to not perform a cache lookup before responding, in which case the Snoop response must be SnpResp_I.

The Snoopee is permitted to include the precise cache state in the response.

A Snoop response can include DataPull only if the cache state in the response is precise.

The Snoopee can include a DataPull in response to a SnpStashUnique only if the cache-data is not present, or present in a Shared state. The Snoopee can include DataPull in response to SnpStashShared only if the cache cache-data is not present.

A DataPull request in a Snoop response to SnpStashUnique must be treated as a ReadUnique request. A DataPull request in a Snoop response to SnpStashShared must be treated as a ReadNotSharedDirty request.

The inclusion of DataPull in the Snoop response must ensure that the initial state must not violate the initial state conditions permitted for the corresponding independent Read requests. See [Read transactions on page 4-173](#).

[Table 4-48](#) shows the Snoopee cache state transitions, the required Snoop responses, and DataPull options for SnpStashUnique.

Table 4-48 Snoop response to SnpStashUnique

Snoop request type	Cache state			RetToSrc	Snoop response
	Initial	Final	Others permitted		
	Expected				
SnpStashUnique	I	I	-	0	SnpResp_I
					SnpResp_I_Read
	UC	UC	-	0	SnpResp_UC
					SnpResp_I
	UCE	UCE	-	0	SnpResp_UC
					SnpResp_UC_Read
					SnpResp_I
	UD	UD	-	0	SnpResp_UD
					SnpResp_I
	UDP	UDP	-	0	SnpResp_UD
					SnpResp_I
	SC	SC	-	0	SnpResp_SC
					SnpResp_SC_Read
					SnpResp_I
	SD	SD	-	0	SnpResp_SD
					SnpResp_SD_Read
					SnpResp_I

Table 4-49 shows the Snoopee cache state transitions, the required Snoop responses, and Data Pull options for SnpStashShared.

Table 4-49 Snoop response to SnpStashShared

Snoop request type	Cache state		RetToSrc	Snoop response
	Initial	Final		
	Expected	Others permitted		
SnpStashShared	I	I	-	0
				SnpResp_I_Read
				SnpResp_I
	UC	UC	-	0
				SnpResp_UC
				SnpResp_I
	UCE	UCE	-	0
				SnpResp_UC
				SnpResp_UC_Read
				SnpResp_I
	UD	UD	-	0
				SnpResp_UD
				SnpResp_I
	UDP	UDP	-	0
				SnpResp_UD
				SnpResp_I
	SC	SC	-	0
				SnpResp_SC
				SnpResp_I
	SD	SD	-	0
				SnpResp_SD
				SnpResp_I

4.8.3 Forwarding Snoop transactions

Forwarding (Fwd) type snoops are used by Home to support DCT. The Forwarding Snoop transactions are:

- [SnpOnceFwd on page 4-242](#)
- [SnpCleanFwd, SnpNotSharedDirtyFwd on page 4-244](#)
- [SnpSharedFwd on page 4-245](#)
- [SnpUniqueFwd on page 4-246](#)
- [SnpPreferUnique and SnpPreferUniqueFwd on page 4-247](#)

The rules, common to all Forwarding snoops at the Snoopee are:

- Expected, but not required, to forward a copy of the cache line to the Requester if the cache line is in one of the following states:
 - UD
 - UC
 - SD
 - SC
- The Snoopee is permitted, but not expected, to convert the Snoop to its corresponding Non-forwarding type.

- Must not forward data in Unique state in response to a Non-invalidating type snoop.
- Snoopee receiving a Snoop request with the DoNotGoToSD bit set, except when the Snoop is SnpOnceFwd, must not transition to SD, even if the coherency conditions permit it.
- In certain cases, based on the Snoop type, the state of the cache line at the Snoopee, and the RetToSrc value in the Snoop request, the Snoopee forwards a copy to Home along with a copy to the Requester. Forwarding snoops must not be used if the original request requests tags.
If tags are available, Clean tags are permitted to be forwarded to the Requester along with the data.
- Home is not permitted to send a Forwarding type snoop for:
 - Atomic transactions
 - Passing Exclusive read transactions

Note

Exclusive read transactions that fail due to Non-exclusive support for the address range being accessed are treated as corresponding Non-exclusive reads, Home can therefore use Forwarding type snoops in these cases.

For the rules that are specific to a particular Forwarding snoop see the individual sub-sections in [Forwarding Snoop transactions](#) on page 4-240.

The tables in the following individual sub-sections show the Snoopee state transitions and the corresponding responses to the Requester and the Home.

The first column in the tables shows the initial cache state, and is the combined data and tag state. [Table 4-50](#) shows the combined state used and the corresponding data and possible tag state combinations.

Table 4-50 Combined state and the corresponding data and tag states

Combined state	Data state	Tag state
I	I	I
UC	UC	I Clean
UCE	UCE	I
UD	UD	I Clean Dirty
UDP	UDP	I
SC	SC	I Clean
SD	SD	I Clean Dirty

The last three columns in the tables correspond to the TagOp value in the Data responses to Home. They are organized, based on the initial state of the tags:

Dirty

Two columns:

- First column: Indicates if the transition itself is permitted or not. This column is only relevant when the tag initial state is Dirty.

Table 4-51 shows the conventions used, P and NP are only relevant when the data initial state is UD or SD and the tag initial state is Dirty.

Table 4-51 Key to table conventions

Symbol	Description
P	The transition is permitted
NP	The transition is not permitted
-	TagOp is not applicable

- Second column: The response TagOp value when the transition is permitted. The TagOp value in the response:
 - Must be *Update* if the response state includes Pass Dirty.
 - Must be *Transfer* if the response does not include Pass Dirty.

Invalid, Clean

One column:

- TagOp in the response can be:
 - *Invalid* if the initial tag state is Invalid or Clean.
 - *Transfer* when the initial tag state is Clean.

In Snoop responses to Home without data, TagOp is inapplicable.

SnpOnceFwd

The rules, in addition to the common rules, to be followed by a Snoopee that receives a SnpOnceFwd are:

- Snoopee must forward the cache line in I state.
 - As a consequence, the Snoopee must not forward Pass Dirty to the Requester.
- Snoopee must return data to Home only when Dirty state is changed to Clean or Invalid.
- RetToSrc bit in the snoop must be set to zero.
- Snoopee can ignore the DoNotGoToSD value in the snoop.

Table 4-52 shows the Snoopee cache state transitions and the required Snoop responses.

See Table 4-51 for the symbol key.

Table 4-52 SnpOnceFwd Snoopee state transitions with Clean and Dirty tags

Snoopee cache state		Response to				TagOp value in response to Home		
Initial	Final	Other permitted	RetToSrc	Requester	Home	Initial tag state		
	Expected					Dirty	I. Clean	
I	I	-	0	No Fwd	SnpResp_I	-	-	-
UC	UC	-	0	CompData_I	SnpResp_UC_Fwded_I	-	-	-
	SC	I	0	CompData_I	SnpResp_SC_Fwded_I	-	-	-
	I	-	0	CompData_I	SnpResp_I_Fwded_I	-	-	-

Table 4-52 SnpOnceFwd Snoopee state transitions with Clean and Dirty tags (continued)

Snoopee cache state		Response to				TagOp value in response to Home		
Initial	Final	Other permitted	RetToSrc	Requester		Initial tag state		
	Expected				Home	Dirty	I. Clean	
UCE	UCE	-	0	No Fwd	SnpResp_UC	-	-	-
	I	-	0	No Fwd	SnpResp_I	-	-	-
UD	UD	-	0	CompData_I	SnpResp_UD_Fwded_I	P ^a	-	-
	SD	-	0	CompData_I	SnpResp_SD_Fwded_I	P ^a	-	-
	SC	I	0	CompData_I	SnpRespData_SC_PD_Fwded_I	P	Update ^b	I, Transfer ^c
	I	-	0	CompData_I	SnpRespData_I_PD_Fwded_I	P	Update	I, Transfer
UDP	UDP	-	0	No Fwd	SnpRespDataPtl_UD	-	-	I
	I	-	0	No Fwd	SnpRespDataPtl_I_PD	-	-	I
SC	SC	I	0	No Fwd	SnpResp_SC	-	-	-
				CompData_I	SnpResp_SC_Fwded_I	-	-	-
	I	-	0	No Fwd	SnpResp_I	-	-	-
				CompData_I	SnpResp_I_Fwded_I	-	-	-
SD	SD	-	0	CompData_I	SnpResp_SD_Fwded_I	P ^a	-	-
	SC	I	0	CompData_I	SnpRespData_SC_PD_Fwded_I	P	Update	I. Transfer
	I	-	0	CompData_I	SnpRespData_I_PD_Fwded_I	P	Update	I. Transfer

- a. This transition is permitted, even though the Snoop response does not include data and the tag state is Dirty, because Dirty tags are retained by the Snoopee.
- b. This transition from tag state of Dirty is permitted because a Dirty copy of tags and data are passed to the Home.
- c. This transaction from an initial state of Dirty data, and Invalid or Clean tags, includes the Snoop response of data with Clean tags when available.

SnpCleanFwd, SnpNotSharedDirtyFwd

The rules, in addition to the common rules, to be followed by a Snoopee that receives a SnpCleanFwd or a SnpNotSharedDirtyFwd are:

- Snoopee must forward the cache line in SC state.
- Snoopee must transition to either SD, SC, or I state.
- For behavior related to the RetToSrc bit see [Returning Data with Snoop response on page 4-251](#).

Table 4-53 shows the Snoopee cache state transitions and the required Snoop responses.

See Table 4-51 on page 4-242 for the symbol key.

Table 4-53 SnpCleanFwd and SnpNotSharedDirtyFwd Snoopee state transitions with Clean and Dirty tags

Snoopee cache (data+tag) state		Response to				TagOp value in response to Home		
Initial	Final	Other permitted	RetToSrc	Requester	Home	Initial tag state		
	Expected					Dirty	I, Clean	
I	I	-	X ^a	No Fwd	SnpResp_I	-	-	-
UC	SC	I	0	CompData_SC	SnpResp_SC_Fwded_SC	-	-	-
			1	CompData_SC	SnpRespData_SC_Fwded_SC	-	-	I, Transfer
	I	-	0	CompData_SC	SnpResp_I_Fwded_SC	-	-	-
			1	CompData_SC	SnpRespData_I_Fwded_SC	-	-	I, Transfer
UCE	I	-	X ^a	No Fwd	SnpResp_I	-	-	-
UD	SD ^b	-	0	CompData_SC	SnpResp_SD_Fwded_SC	P	-	-
			1	CompData_SC	SnpRespData_SD_Fwded_SC	P	Transfer	I, Transfer
	SC	I	X ^a	CompData_SC	SnpRespData_SC_PD_Fwded_SC	P	Update	I, Transfer
	I	-	X ^a	CompData_SC	SnpRespData_I_PD_Fwded_SC	P	Update	I, Transfer
UDP	I	-	X ^a	No Fwd	SnpRespDataPtl_I_PD	-	-	I
SC	SC	I	0	CompData_SC	SnpResp_SC_Fwded_SC	-	-	-
			1	CompData_SC	SnpRespData_SC_Fwded_SC	-	-	I, Transfer
	I	-	0	CompData_SC	SnpResp_I_Fwded_SC	-	-	-
			1	CompData_SC	SnpRespData_I_Fwded_SC	-	-	I, Transfer
SD	SD ^b	-	0	CompData_SC	SnpResp_SD_Fwded_SC	P	-	-
			1	CompData_SC	SnpRespData_SD_Fwded_SC	P	Transfer	I, Transfer
	SC	I	X ^a	CompData_SC	SnpRespData_SC_PD_Fwded_SC	P	Update	I, Transfer
	I	-	X ^a	CompData_SC	SnpRespData_I_PD_Fwded_SC	P	Update	I, Transfer

a. The protocol requirements apply for both states of RetToSrc.

b. This state transition is not permitted if DoNotGoToSD is asserted.

SnpSharedFwd

The rules, in addition to the common rules, to be followed by a Snoopee that receives a SnpSharedFwd are:

- Snoopee is permitted to forward the cache line in either SD or SC state.
- Snoopee must transition to either SD, SC, or I state.
- For behavior related to the RetToSrc bit see [Returning Data with Snoop response on page 4-251](#).

Table 4-54 shows the Snoopee cache state transition and the required Snoop responses.

See Table 4-51 on page 4-242 for the symbol key.

Table 4-54 SnpSharedFwd Snoopee state transitions with Clean and Dirty tags

Snoopee cache state		Response to			TagOp value in response to Home		
Initial	Final	Other permitted	RetToSrc	Requester	Home	Initial tag state

SC	SC	I	0	CompData_SC	SnpResp_SC_Fwded_SC	-	-
			1	CompData_SC	SnpRespData_SC_Fwded_SC	-	I, Transfer
	I	-	0	CompData_SC	SnpResp_I_Fwded_SC	-	-
			1	CompData_SC	SnpRespData_I_Fwded_SC	-	I, Transfer

Table 4-54 SnpSharedFwd Snoopee state transitions with Clean and Dirty tags (continued)

Snoopee cache state		Response to			TagOp value in response to Home			
Initial	Final	Other permitted	RetToSrc	Requester	Home	Initial tag state		
	Expected					Dirty	I, Clean	
SD	SD ^b	-	0	CompData_SC	SnpResp_SD_Fwded_SC	P	-	-
			1	CompData_SC	SnpRespData_SD_Fwded_SC	P	Transfer	I, Transfer
	SC	I	0	CompData_SD_PD	SnpResp_SC_Fwded_SD_PD	NP	-	-
			1	CompData_SD_PD	SnpRespData_SC_Fwded_SD_PD	NP	-	I, Transfer
			X ^a	CompData_SC	SnpRespData_SC_PD_Fwded_SC	P	Update	I, Transfer
	I	-	0	CompData_SD_PD	SnpResp_I_Fwded_SD_PD	NP	-	-
			1	CompData_SD_PD	SnpRespData_I_Fwded_SD_PD	NP	-	I, Transfer
			X ^a	CompData_SC	SnpRespData_I_PD_Fwded_SC	P	Update	I, Transfer

a. The protocol requirements apply for both states of RetToSrc.

b. This state transition is not permitted if DoNotGoToSD is asserted.

SnpUniqueFwd

Use of the SnpUniqueFwd snoop is only permitted if the cache line is cached at a single RN-F:

- Home is permitted to send the SnpUniqueFwd snoop to an RN-F in Shared state if Home determines that the Invalidating snoop needs to be sent to only one cache.

The rules, in addition to the common rules, to be followed by a Snoopee that receives a SnpUniqueFwd are:

- Snoopee must forward the cache line in Unique state.
- Snoopee that has the cache line in Dirty state must Pass Dirty to the Requester not to Home.
- Snoopee must transition to I state.
- Snoopee must not return data to Home.

RetToSrc bit in the snoop must be set to zero.

[Table 4-55 on page 4-247](#) shows the Snoopee cache state transitions and the required Snoop responses.

See [Table 4-51 on page 4-242](#) for the symbol key.

Table 4-55 SnpUniqueFwd Snoopee state transitions with Clean and Dirty tags

Snoopee cache (data+tags) state		Response to			TagOp value in response to Home			
Initial	Final	Expected	Other permitted	RetToSrc	Requester	Home	Initial tag state	
							Dirty	I, Clean
I	I	-	-	0	No Fwd	SnpResp_I	-	-
UC	I	-	-	0	CompData_UC	SnpResp_I_Fwded_UC	-	-
UCE	I	-	-	0	No Fwd	SnpResp_I	-	-
UD	I	-	-	0	CompData_UD_PD	SnpResp_I_Fwded_UD_PD	NP ^a	-
					No Fwd	SnpRespData_I_PD	P	Update
UDP	I	-	-	0	No Fwd	SnpRespDataPtl_I_PD	-	I
SC	I	-	-	0	CompData_UC	SnpResp_I_Fwded_UC	-	-
SD	I	-	-	0	CompData_UD_PD	SnpResp_I_Fwded_UD_PD	NP ^a	-
					No Fwd	SnpRespData_I_PD	P	Update

- a. This transition is not permitted because Dirty tags are lost. The Dirty tags are lost because the Snoop response to the Home does not include data with which to pass the Dirty tags to the Home.

SnpPreferUnique and SnpPreferUniqueFwd

Use of the SnpPreferUniqueFwd snoop is only permitted if the cache line is cached at a single RN-F.

The rules, in addition to the common rules, to be followed by a Snoopee that receives a SnpPreferUniqueFwd and does not treat it as the Non-forwarding snoop are:

- When the Snoopee is in the process of executing an Exclusive access sequence, using the same address:
 - Snoopee must forward the cache line in SC state.
 - Snoopee must transition to either SD or SC state.
 - Snoopee must not transition to I state, except when in UCE or UDP state.
 - For behavior related to the RetToSrc bit see [Returning Data with Snoop response on page 4-251](#) related to SnpNotSharedDirtyFwd.
 - A Snoopee that is not in the middle of executing an Exclusive access sequence is permitted, but not expected, to treat the snoop as a Non-invalidating snoop.
- When the Snoopee is not in the process of executing an Exclusive access sequence, using the same address, and treats the snoop as an Invalidating snoop:
 - Snoopee must forward the cache line in Unique state.
 - Snoopee that has the cache line in Dirty state must Pass Dirty to the Requester not to Home.
 - Snoopee must transition to I state.
 - Snoopee must not return data to Home.
 - RetToSrc bit value in the snoop is ignored and treated as zero.

For SnpPreferUnique and SnpPreferUniqueFwd, it is IMPLEMENTATION DEFINED when an agent is in the process of executing an exclusive sequence. This specification cannot determine whether a Snoopee will treat SnpPreferUnique as an invalidating snoop or a non-invalidating snoop. To determine this, the Snoop response must be inspected. It is protocol compliant for a Snoopee to always treat the snoop as non-invalidating.

Table 4-56 and Table 4-57 on page 4-250 show the Snoopee cache state transitions and the required Snoop responses.

See Table 4-51 on page 4-242 for the symbol key.

Table 4-56 State transitions for SnpPreferUniqueFwd when Snoopee is executing an exclusive sequence

Snoopee cache (Data+tag) state			Response to			TagOp value in response to Home		
Initial	Final		RetToSrc	Requester	Home	Initial tag state		
	Expected	Other Permitted				Dirty	I, Clean	
I	I	-	X	No Fwd	SnpResp_I	-	-	-
UC	SC	-	0	CompData_SC	SnpResp_SC_Fwded_SC	-	-	-
			1	CompData_SC	SnpRespData_SC_Fwded_SC	-	-	I, Transfer
UCE	I	-	X	No Fwd	SnpResp_I	-	-	-
UD	SD*	-	0	CompData_SC	SnpResp_SD_Fwded_SC	P	-	-
			1	CompData_SC	SnpRespData_SD_Fwded_SC	P	Transfer	I, Transfer
	SC	-	X	CompData_SC	SnpRespData_SC_PD_Fwded_SC	P	Update	I, Transfer
UDP	I	-	X	No Fwd	SnpRespDataPtl_I_PD	-	-	I
SC	SC	-	0	CompData_SC	SnpResp_SC_Fwded_SC	-	-	-
			1	CompData_SC	SnpRespData_SC_Fwded_SC	-	-	I, Transfer
SD	SD*	-	0	CompData_SC	SnpResp_SD_Fwded_SC	P	-	-
			1	CompData_SC	SnpRespData_SD_Fwded_SC	P	Transfer	I, Transfer
	SC	-	X	CompData_SC	SnpRespData_SC_PD_Fwded_SC	P	Update	I, Transfer

Table 4-57 shows the expected and permitted Snoopee cache state transitions and responses to the SnpPreferUniqueFwd Snoop request when the Snoopee is not executing an Exclusive sequence.

See Table 4-51 on page 4-242 for the symbol key.

Table 4-57 State transitions for SnpPreferUniqueFwd when Snoopee is not executing an exclusive sequence

Snoopee cache (data+tag) state			Response to			TagOp value in response to Home		
Initial	Final	Other Permitted	RetToSrc	Requester	Home	Initial tag state		
	Expected					Dirty	I, Clean	
I	I	-	X	No Fwd	SnpResp_I	-	-	-
UC	I	-	X	CompData_UC	SnpResp_I_Fwded_UC	-	-	-
UCE	I	-	X	No Fwd	SnpResp_I	-	-	-
UD	I	-	X	CompData_UD_PD	SnpResp_I_Fwded_UD_PD	NP	-	-
			X	No Fwd	SnpRespData_I_PD	P	Update	I, Transfer
UDP	I	-	X	No Fwd	SnpRespDataPtl_I_PD	-	-	I
SC	I	-	X	CompData_UC	SnpResp_I_Fwded_UC	-	-	-
SD	I	-	X	CompData_UD_PD	SnpResp_I_Fwded_UD_PD	NP		
			X	No Fwd	SnpRespData_I_PD	P	Update	I, Transfer

4.9 Returning Data with Snoop response

The rules for returning a copy of the cache line with the Snoop response are detailed below.

For Non-forwarding snoops, except SnpMakeInvalid, the rules for returning a copy of the cache line to the Home are:

- Irrespective of the value of RetToSrc, must return a copy if the cache line is Dirty.
- Irrespective of the value of RetToSrc, optionally can return a copy if the cache line is Unique Clean.
- If the RetToSrc value is 1, must return a copy if the cache line is Shared Clean and the Snoopee retains a copy of the cache line.
- If the RetToSrc value is 0, must not return a copy if the cache line is Shared Clean.

For Forwarding snoops where data is being forwarded, the rules for returning a copy of the cache line to the Home are:

- Irrespective of the value of RetToSrc, must return a copy if a Dirty cache line cannot be forwarded or kept.
- If the RetToSrc value is 1, must return a copy if the cache line is Dirty or Clean.
- If the RetToSrc value is 0, must not return a copy if the cache line is Clean.

RetToSrc is inapplicable and must be set to zero in:

- SnpQuery and Stash snoops
- SnpCleanShared, SnpCleanInvalid, and SnpMakeInvalid
- SnpOnceFwd and SnpUniqueFwd

RetToSrc is applicable and can take any value in all other snoops except SnpDVMOp.

RetToSrc is inapplicable and must be set to zero in SnpDVMOp.

Home must only set RetToSrc on the Snoop request to a single Request Node.

4.10 Do not transition to SD

Do not transition to SD is a modifier on Non-invalidating snoops.

It specifies when a Snoopee must not transition to SD state as a result of the Snoop request.

The field name is DoNotGotoSD.

———— **Note** ————

- A non-forced change or silent change from UD to SD is permitted irrespective of the value of DoNotGoToSD.
- Any forced change from Unique to Shared must obey DoNotGoToSD.

See [Do not transition to SD state, DoNotGoToSD on page 13-442](#) for the field applicability and field value encoding.

4.11 Hazard conditions

This section lists the responsibilities of the RN-F and HN-F to handle address hazards and race conditions among Snoopable transactions. Ordering among Non-snoopable transactions and among Snoopable transactions is described in [Ordering on page 2-121](#).

In addition to many Requesters issuing transactions at the same time, the protocol also permits each Requester to make multiple outstanding requests, and to receive multiple outstanding snoop requests. It is the responsibility of the interconnect, that is, ICN(HN-F, HN-I and MN), to ensure that there is a defined order in which transactions to the same cache line can occur, and that the defined order is the same for all components.

4.11.1 At the RN-F node

An RN-F node must respond to received Snoop requests, except for SnpDVMOp(Sync), in a timely manner without creating any Protocol layer dependency on completion of outstanding requests.

If a pending request to the same cache line is present at the RN-F and the pending request has not received any Data response packets:

- The Snoop request must be processed normally.
- The cache state must transition as applicable for each Snoop request type.
- The cached data or CopyBack request data must be returned with the Snoop response, or forwarded to the Requester, if required by the Snoop request type, Snoop request attributes, and cache state.

If a pending request to the same cache line is present at the RN-F and the pending request has received at least one Data response packet:

- The RN-F must wait to receive all Data response packets before responding to the Snoop request.
- Once all the Data response packets are received by RN-F:
 - The Snoop request must be processed normally.
 - The cache state must transition as applicable for each Snoop request type.
 - The cached data must be returned with the Snoop response, or forwarded to the Requester, if required by the Snoop request type, Snoop request attributes, and cache state.

If the pending request is a CopyBack request then the following additional requirements apply:

- Request transaction flow must be completed after receiving the CompDBIDResp.
- The cache state in the CopyBackWrData response must be the state of the cache line after the snoop request is processed, not the state at the time of sending the CopyBack request.
- If the cache line state is I after the Snoop response is sent, the cache state in CopyBackWrData response must be I, all byte enables must be deasserted, and the corresponding data must be set to zero.
- If the cache line state is UC or SC after the Snoop response is sent, a Request Node is permitted to not send valid CopyBack Data. If the Request Node decides not to send valid CopyBack data, the cache state in the CopyBackWrData response must be I, all byte enables must be deasserted, and the corresponding data must be set to zero.
- If data is included with CopyBackWrData, it can be:
 - The same data that has been sent with the Snoop response
 - More up to date data than sent with the snoop response.
This is only possible when the snoop is SnpOnce, SnpOnceFwd, or SnpCleanShared, and the snoop response indicates the cache line can be further modified.
 - Older data than was sent with the snoop response.
This is only possible when the CopyBack write is a WriteClean, the snoop request is SnpOnce*, and the response indicates that the cache line can be further modified.

For non-ordered transactions, the Request Node can send CompAck without waiting for DataSepResp. For ordered transactions, the Request Node can send CompAck as soon as the first packet of DataSepResp is received. In both cases, a Request Node must not respond to a Snoop request before receiving all data packets.

The RN-F might receive multiple snoop requests before it receives a response for a pending CopyBack request for the same cache line. In this instance, the data response carries the cache line state after the completion of the response to the last snoop request. Such a scenario is possible because the CopyBack request can be queued behind multiple Read and Dataless requests at the HN-F.

4.11.2 At the ICN(HN-F) node

An HN-F orders transactions to the same cache line by sequencing transaction responses and Snoop transactions to the Requesters. As the interconnect is not required to be ordered, the arrival order of these messages, in certain cases, might not be the same as the order in which they were issued at the HN-F.

If a Response message that includes data requires multiple packets or beats of transfers over the interconnect, receiving or sending the message by Home implies sending or receiving all the packets corresponding to that message. That is, when a Home starts sending the message, it must send all packets of the message without dependence on completion of any other request or response message.

Similarly, when a Home accepts part of the Data message, it must accept the remaining packets of that message without any dependence on forward progress of any other request or response message.

When a subsequent forwarding of data depends upon receiving a Data message, the forwarding of data action can occur after receiving the first Data packet. A subsequent Non-data forwarding action that is processing of a subsequent request at Home as a consequence of sending or receiving of data by Home, must wait until all data is sent or received.

While a Snoop transaction response is pending, the only transaction responses that are permitted to be sent to the same address are:

- RetryAck for a CopyBack
- RetryAck and DBIDResp for a WriteUnique and Atomics
- RetryAck and, if applicable, a ReadReceipt for a Read request type
- RetryAck for a Dataless request type

Once a completion is sent for a transaction, the HN-F must not send a Snoop request to the same cache line until it receives:

- A CompAck for any Read and Dataless requests except for ReadOnce* and ReadNoSnp.
- A WriteData response for CopyBack and Atomic requests.
- For WriteUnique, a WriteData response, and, if applicable, CompAck.

Chapter 5

Interconnect Protocol Flows

This chapter shows interconnect protocol flows for different transaction types, and interconnect hazard conditions. The protocol flows are illustrated using Time-Space diagrams. It contains the following sections:

- [Read transaction flows on page 5-256](#)
- [Dataless transaction flows on page 5-266](#)
- [Write transaction flows on page 5-270](#)
- [Atomic transaction flows on page 5-273](#)
- [Stash transaction flows on page 5-280](#)
- [Hazard handling examples on page 5-283](#)

See [Time-Space diagrams on page xv](#) for details of the conventions used to illustrate protocol flow in this specification.

In the transaction flow diagrams that follow:

- There are multiple coherent Request Nodes, an HN-F, and an SN-F.
- If the HN-F receives multiple data responses, that is, one response from a snooped RN-F and another from an SN-F, then the data being forwarded to the Requester is highlighted in bold.
- There is no interconnect cache at the HN-F. This results in all requests to the HN-F initiating a request to the SN-F.

5.1 Read transaction flows

This section gives examples of the interconnect protocol flow for Read transactions.

5.1.1 Read transactions with DMT and without snoops

For Read transactions without snoops, it is recommended to use DMT.

Figure 5-1 shows an example DMT transaction flow using the ReadShared transaction.

In Figure 5-1, a response from SN-F to HN-F is not required because CompAck from the Requester is used to deallocate the request at Home.

Figure 5-1 DMT Read transaction example without snoops

The steps in the ReadShared transaction flow in Figure 5-1 are:

1. RN-F sends a ReadShared request to HN-F.
2. HN-F sends a ReadNoSnp request to SN-F.
3. SN-F sends a data response directly to RN-F, using CompData_UC.
4. RN-F sends CompAck to HN-F as the request is ReadShared and requires CompAck to complete the transaction.

5.1.2 Read transaction with DMT and with snoops

For Read transactions with snoops and data from memory, DMT is recommended.

Figure 5-2 shows an example DMT transaction flow using the ReadShared transaction.

From SN-F to HN-F, a response is not required because CompAck from the Requester is used to deallocate the request at Home.

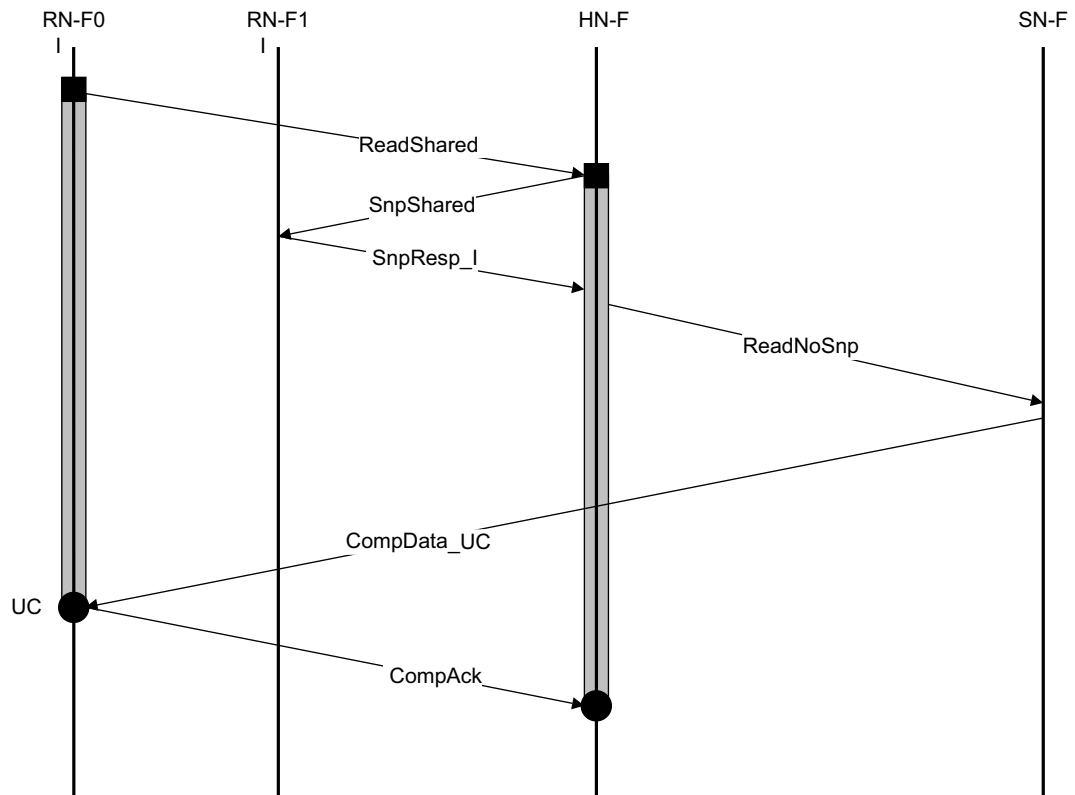

Figure 5-2 DMT Read transaction example with snoops and data from memory

The steps in the ReadShared transaction flow in Figure 5-2 are:

1. RN-F0 sends a ReadShared request to HN-F.
2. HN-F sends a SnpShared request to RN-F1. RN-F1 returns SnpResp_I response to HN-F.
3. HN-F sends a ReadNoSnp request to SN-F after receiving the Snoop response from RN-F1. This guarantees that RN-F1 has not responded with data.
4. SN-F sends a data response directly to RN-F0, using CompData_UC.
5. RN-F0 sends CompAck to HN-F as the request is ReadShared and requires CompAck to complete the transaction.

5.1.3 Read transaction with DCT

For Read transactions with snoops and data from other Request Node caches, *Direct Cache Transfer* (DCT) is recommended.

DCT from cache line in UC state

Figure 5-3 shows an example flow for a DCT transaction. The Requester is RN-F0 and the forwarding cache is at RN-F1.

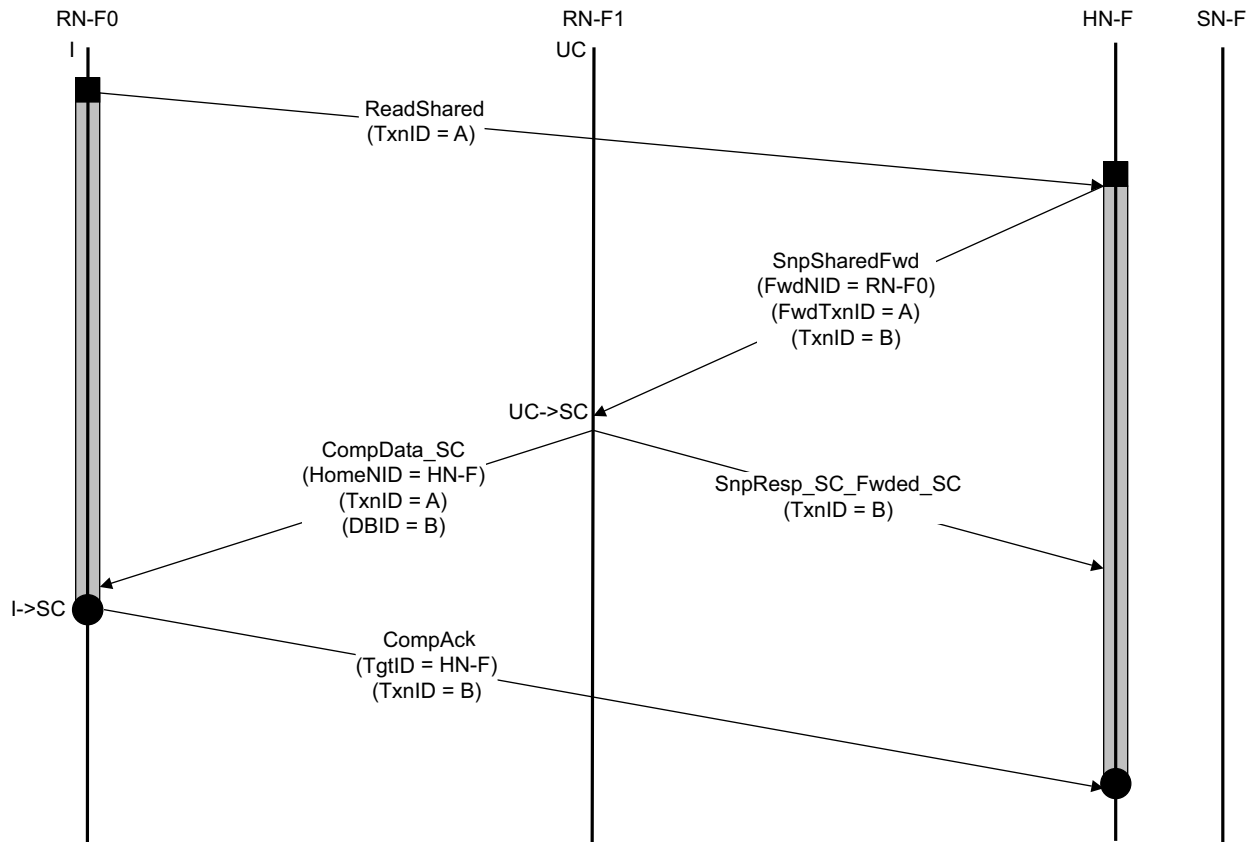

Figure 5-3 Direct Cache Transfer from cache line in UD state

The steps in the DCT transaction flow in Figure 5-3 are:

1. RN-F0 sends a ReadShared request to HN-F.
2. HN-F sends a SnpSharedFwd, a Forwarding snoop request to RN-F1.
3. RN-F1 forwards CompData_SC response to RN-F0. The TxnID is the same as the original ReadShared request.
4. RN-F1 also sends a SnpResp_SC_Fwded_SC snoop response to HN-F. RN-F1 cache line state transitions from UC to SC.
5. After receiving the CompData_SC response, RN-F0 cache line state transitions from I to SC and RN-F0 sends a CompAck response to HN-F.

———— **Note** ————

Steps 3 and 4 in the DCT transaction flow can occur in any order as CompData and SnpResp are sent on different channels.

Double data return in a DCT transaction

Figure 5-4 shows an example DCT transaction flow that sends the data to HN-F and forwards the data to the RN-F0.

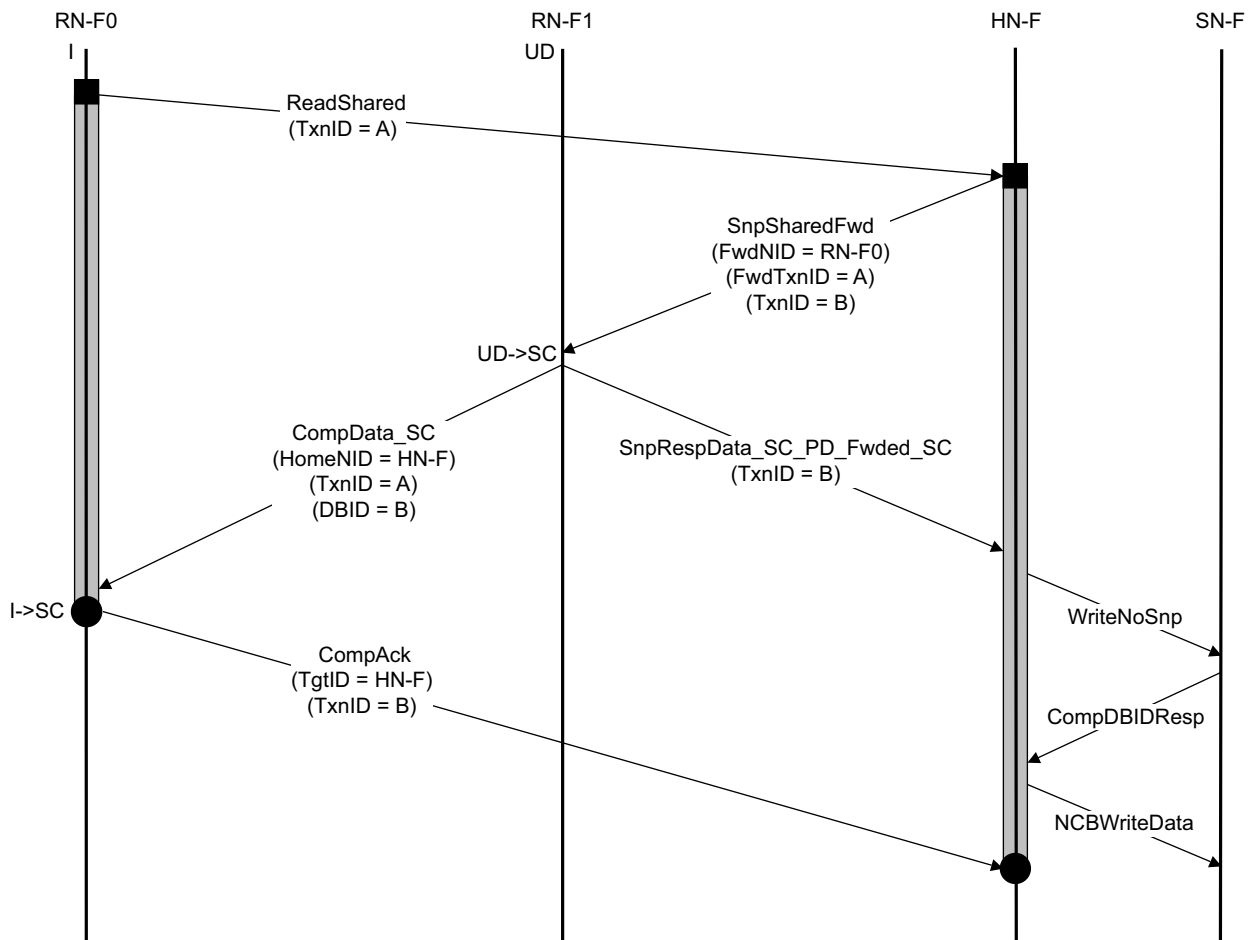

Figure 5-4 Double data return in DCT transaction

The steps in the DCT transaction flow in Figure 5-4 are:

1. RN-F0 sends a ReadShared request to HN-F.
2. HN-F sends a SnpSharedFwd Snoop request to RN-F1.
3. RN-F1 sends CompData_SC response to RN-F0. The TxnID is the same as the original ReadShared request. RN-F0 cache line state transitions from I to SC.
4. RN-F1 also sends a SnpRespData_SC_PD_Fwded_SC Snoop response to HN-F that includes a copy of the cache line and passes responsibility for the Dirty cache line to HN-F. RN-F1 cache line state transitions from UD to SC.

5. HN-F sends a WriteNoSnp request to the SN-F.
6. SN-F responds to the HN-F with CompDBIDResp to request the data.
7. HN-F sends NCBWrData to the SN-F.
8. RN-F0 sends CompAck after it receives the Data response.

5.1.4 Read transaction without DMT or DCT

Figure 5-5 shows an example of the flow without DMT using the ReadNoSnp transaction. In Figure 5-5 the ReadNoSnp has the ExpCompAck set in the original request.

The request does not generate any snoops and receives the data from a response to a memory read by the HN-F.

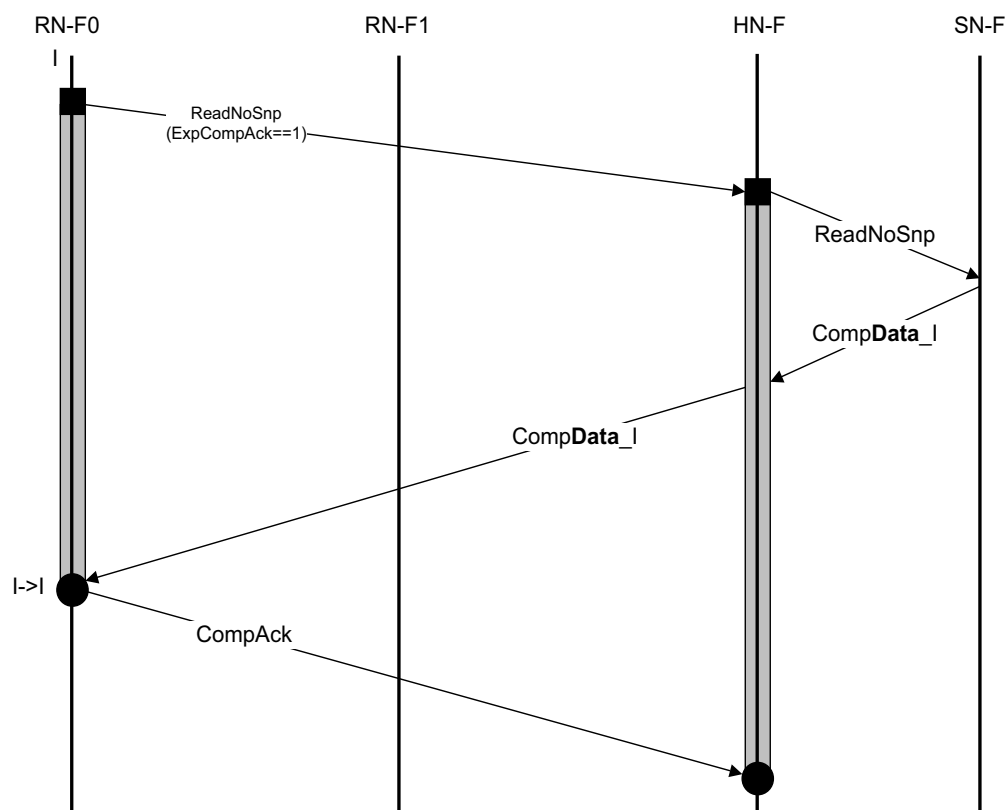

Figure 5-5 ReadNoSnp transaction flow

The steps in the ReadNoSnp transaction flow in Figure 5-5 are:

1. RN-F0 issues a ReadNoSnp transaction, with ExpCompAck set to 1.
2. HN-F receives and allocates the request.

Note

HN-F does not send snoops as the request is recognized as a Non-snooppable request type.

3. HN-F sends a ReadNoSnp to SN-F.
4. SN-F returns CompData_I response to HN-F.
5. HN-F returns the data to RN-F0.

Note

If ExpCompAck had not been asserted in the original ReadNoSnp request, the HN-F could have deallocated the request at this point.

6. RN-F0 deallocates the request and sends CompAck towards the HN-F.
7. HN-F receives the CompAck response and deallocates the request.

The copy of data being transferred is marked in bold in [Figure 5-5 on page 5-260](#).

5.1.5 Read transaction with snoop response with partial data and no memory update

An example of this type of flow is a ReadUnique transaction.

[Figure 5-6](#) shows the transaction flow, the copy of data being transferred is marked in bold.

Figure 5-6 ReadUnique with partial data snoop response

The steps in the ReadUnique with partial data snoop response transaction flow in [Figure 5-6](#) are:

1. RN-F0 sends ReadUnique request to HN-F.
2. HN-F sends ReadNoSnp request to SN-F and SnpUnique requests to RN-F1 and RN-F2.
3. RN-F1 transitions the cache line from UDP to I and returns SnpRespDataPtl_I_PD to HN-F. RN-F2 returns SnpResp_I to the HN-F. Meanwhile, the SN-F returns CompData response to HN-F. HN-F merges the data returned from the SN-F with the partial data received from the RN-F1.
4. HN-F sends CompData_UD_PD to RN-F0. RN-F0 cache line state transitions from I to UD.

5. RN-F0 issues CompAck response to the HN-F to indicate transaction completion.

5.1.6 Read transaction with snoop response with partial data and memory update.

An example of this type of flow is a ReadClean transaction.

Figure 5-7 shows the transaction flow, the copy of data being transferred is marked in bold.

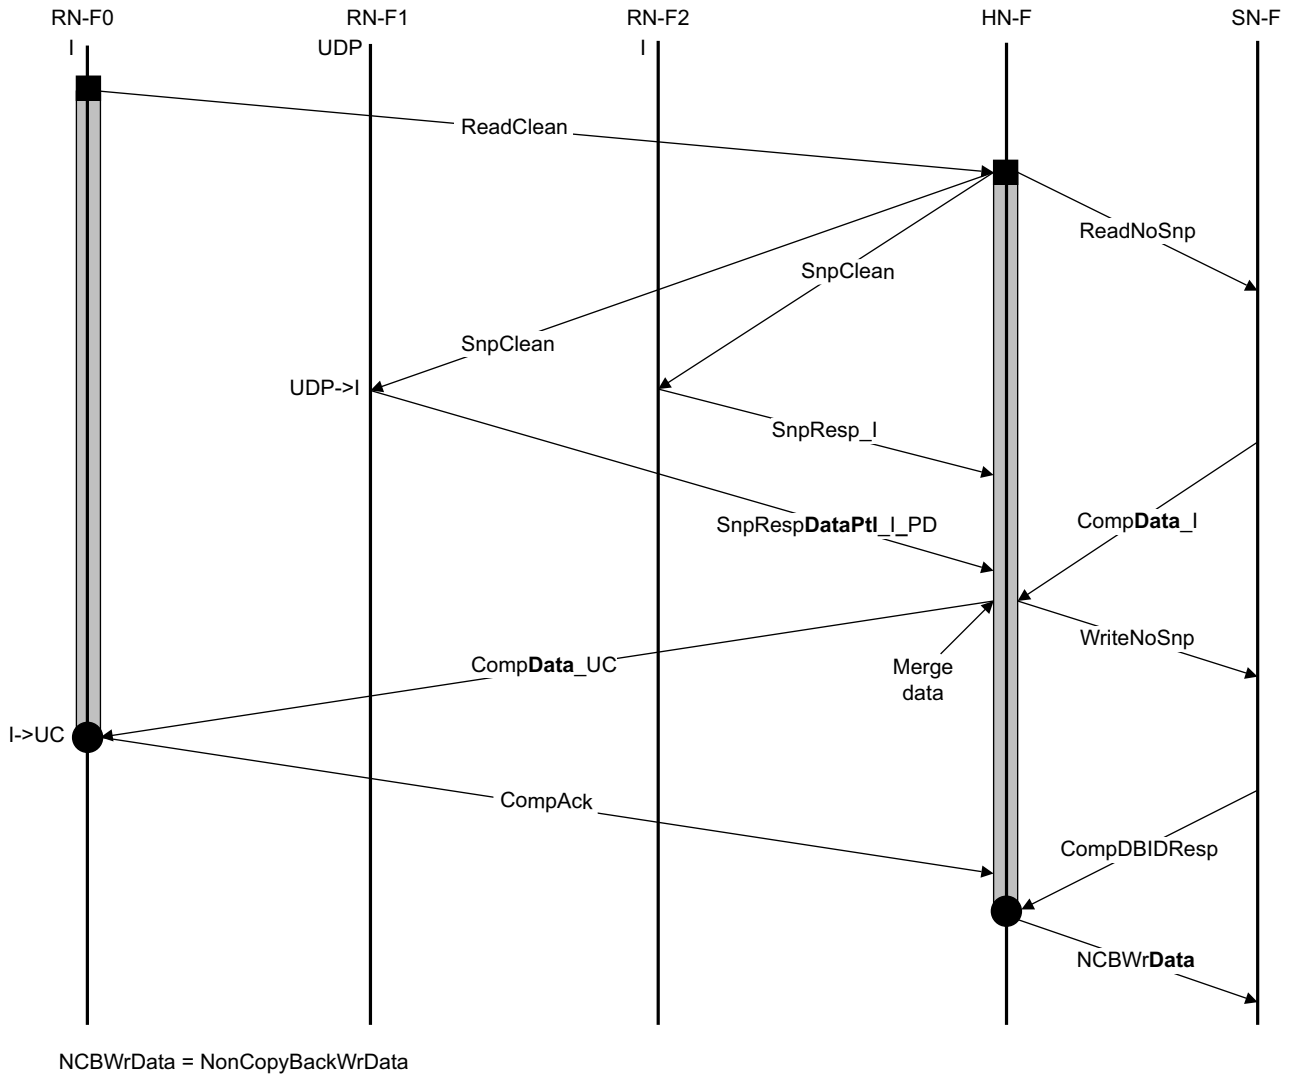

Figure 5-7 ReadClean with partial data snoop response

The steps in the ReadClean with partial data snoop response transaction flow in Figure 5-7 are:

1. RN-F0 sends ReadClean request to HN-F.
2. HN-F sends ReadNoSnp request to SN-F and SnpClean requests to RN-F1 and RN-F2. RN-F1 cache line state transitions from UDP to I.
3. RN-F1 returns SnpRespDataPtl_I_PD and RN-F2 returns SnpResp_I to the HN-F. Meanwhile, the SN-F returns CompData_I response to HN-F. This merges the data.
4. HN-F sends CompData_UC to RN-F0 and WriteNoSnp to SN-F. RN-F0 cache line state transitions from I to UC.
5. RN-F0 issues CompAck response to the HN-F to indicate transaction completion.

6. SN-F issues CompDBIDResp to HN-F.
7. HN-F sends NCBWrData to SN-F.

5.1.7 ReadOnce* and ReadNoSnp with early Home deallocation

Figure 5-8 shows the optimized flow for an unordered ReadOnce request.

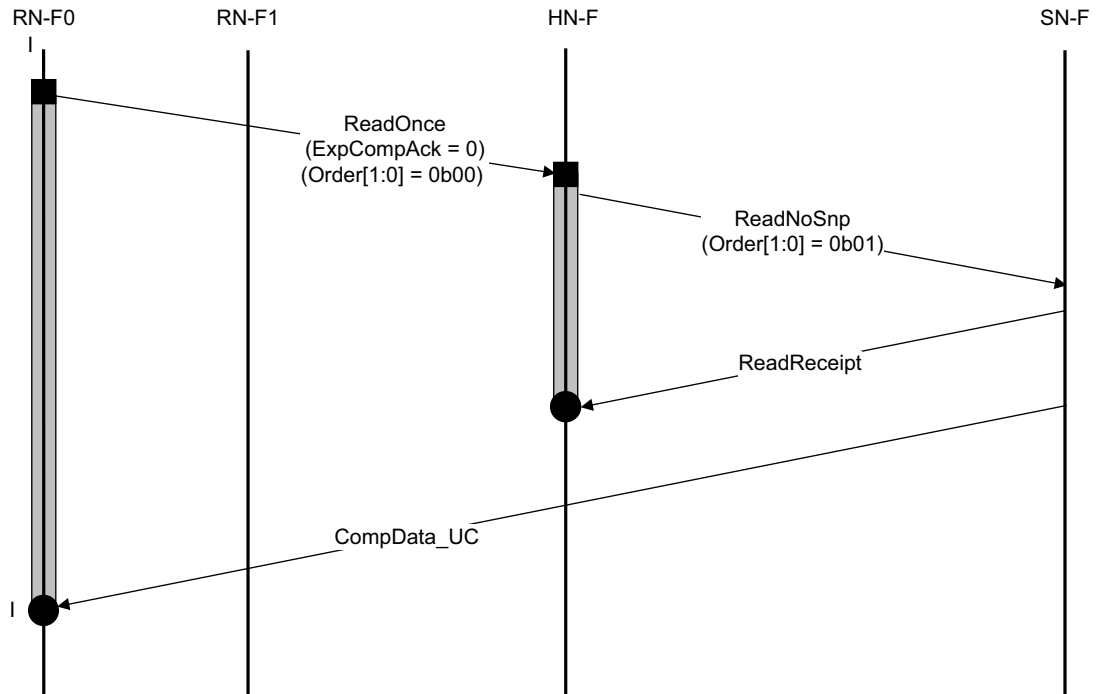

Figure 5-8 DMT optimization for unordered ReadOnce

The steps in the optimized ReadOnce transaction flow in Figure 5-8 are:

1. RN-F0 sends an unordered ReadOnce request to HN-F with Order[1:0] set to 0b00.
2. HN-F sends a DMT ReadNoSnp request to SN-F with the Order[1:0] set to 0b01.
3. SN-F sends ReadReceipt to Home.
4. HN-F deallocates the request after receiving the ReadReceipt response.
5. SN-F sends CompData_UC directly to RN-F0.

Note

Use of a ReadNoSnp transaction from Home to Subordinate, in the case where CompAck is not required, avoids the need to send a RespSepData response from Home to Requester.

5.1.8 ReadNoSnp transaction with DMT and separate Non-data and Data-only response

Figure 5-9 shows an example DMT transaction flow with separate Non-data and Data-only response.

In this example, there is no ordering requirement and RN-F can send CompAck to HN-F to deallocate the request at Home without waiting for DataSepResp.

Figure 5-9 DMT Read transaction example with separate Non-data and Data-only

The steps in the ReadNoSnp transaction in Figure 5-9 are:

1. RN-F sends an unordered ReadNoSnp request to HN-F.
2. HN-F sends a ReadNoSnpSep request to SN-F.
3. HN-F sends a RespSepData response to RN-F.
4. SN-F sends a ReadReceipt to HN-F.
5. RN-F sends CompAck after receiving RespSepData.
6. SN-F sends DataSepResp to RN-F returning the read data.

5.1.9 ReadNoSnp transaction with DMT with ordering and separate Non-data and Data-only

Figure 5-10 shows an example DMT transaction flow with ordering and separate Non-data and Data-only.

ReadNoSnp with non-zero Order field in Figure 5-10 requires that:

- Next ordered request can be sent only after receiving of RespSepData.
- RN-F must wait for RespSepData and at least one packet of DataSepResp before sending CompAck.
- HN-F must not send next ordered request to SN-F until it receives CompAck.

Figure 5-10 DMT Read transaction example with ordering and separate Non-data and Data-only

The steps in the Read transaction with ordering and separate Non-data and Data-only in Figure 5-10 are as follows:

1. RN-F sends ReadNoSnp to HN-F, with ExpCompAck set to 1. Order[1:0] is set to 0b10.
2. HN-F sends ReadNoSnpSep to SN-F with Order[1:0] set to 0b01.
3. HN-F returns RespSepData to RN-F.
4. SN-F returns ReadReceipt to HN-F.
5. SN-F sends DataSepResp to RN-F directly.
6. RN-F issues CompAck to HN-F.

5.2 Dataless transaction flows

This section gives examples of the interconnect protocol flow for Dataless transactions.

5.2.1 Dataless transaction without memory update

An example of this type of flow is a MakeUnique transaction.

Figure 5-11 shows the transaction flow.

Figure 5-11 MakeUnique without memory update

The steps in the MakeUnique without memory update transaction flow in Figure 5-11 are:

1. RN-F0 sends MakeUnique request to HN-F.
2. HN-F sends SnpMakeInvalid requests to RN-F1 and RN-F2. RN-F1 cache line state transitions from UC to I.
3. RN-F1 and RN-F2 return SnpResp_I to the HN-F.
4. HN-F sends Comp_UC to RN-F0. RN-F0 cache line state transitions from I to UD.
5. RN-F0 issues CompAck response to the HN-F to indicate transaction completion.

5.2.2 Dataless transaction with memory update

An example of this type of flow is a CleanUnique transaction.

Figure 5-12 shows the transaction flow.

Figure 5-12 CleanUnique with memory update

The steps in the CleanUnique with memory update transaction flow in Figure 5-12 are:

1. RN-F0 sends CleanUnique request to HN-F.
2. HN-F sends SnpCleanInvalid requests to RN-F1 and RN-F2. RN-F1 cache line state transitions from SD to I.
3. RN-F1 returns SnpRespData_I_PD to HN-F. HN-F sends WriteNoSnp to SN-F.
4. RN-F2 returns SnpResp_I to the HN-F. HN-F can now send Comp_UC to RN-F0. RN-F0 cache line state transitions from SC to UC. Meanwhile, SN-F returns CompDBIDResp to HN-F. HN-F then sends NCBWrData to SN-F.
5. RN-F0 issues CompAck response to the HN-F to indicate transaction completion.

5.2.3 Persistent CMO with snoop and separate Comp and Persist

In this example of CleanSharedPersistSep transaction flow, the PoP is at the SN-F.

Figure 5-13 shows the transaction flow.

Figure 5-13 CleanSharedPersistSep transaction flow

The steps in the CleanSharedPersistSep transaction flow in Figure 5-13 are:

1. RN-F0 sends CleanSharedPersistSep request to HN-F.
2. HN-F sends SnpCleanShared request to RN-F1.
3. RN-F1 sends SnpResp_SC to HN-F.
4. HN-F sends Comp_SC to RN-F0.

5. HN-F sends CleanSharedPersistSep to SN-F after completing the writing back of all snooped Dirty data, if any.

———— **Note** ————

If any Dirty data had been returned to the HN-F following the snoops, the HN-F would need to complete the write back of this data to the SN-F first. Only then could the HN-F issue the CleanSharedPersistSep request to the SN-F.

6. SN-F returns Comp response to HN-F. SN-F directly sends Persist response to RN-F0 to indicate the request has reached PoP and data from any prior writes to the same location is pushed to PoP.

5.2.4 Evict transaction

Figure 5-14 shows the Evict transaction flow.

———— **Note** ————

The Evict request is a hint. A Comp response can be given by HN-F without updating the Snoop Filter or Snoop Directory.

Figure 5-14 Evict transaction flow

The steps in the Evict transaction flow in Figure 5-14 are:

1. RN-F0 cache line state transitions from UC to I and sends Evict request to HN-F. HN-F receives and allocates the request.
2. HN-F returns Comp_I response and deallocates the request. RN-F0 deallocates the request.

———— **Note** ————

The cache state at the Requester must change to Invalid before the Evict message is sent.

5.3 Write transaction flows

This section gives examples of the interconnect protocol flow for Write transactions.

5.3.1 Write transaction with no snoop and separate responses

Figure 5-15 shows a WriteNoSnp transaction flow.

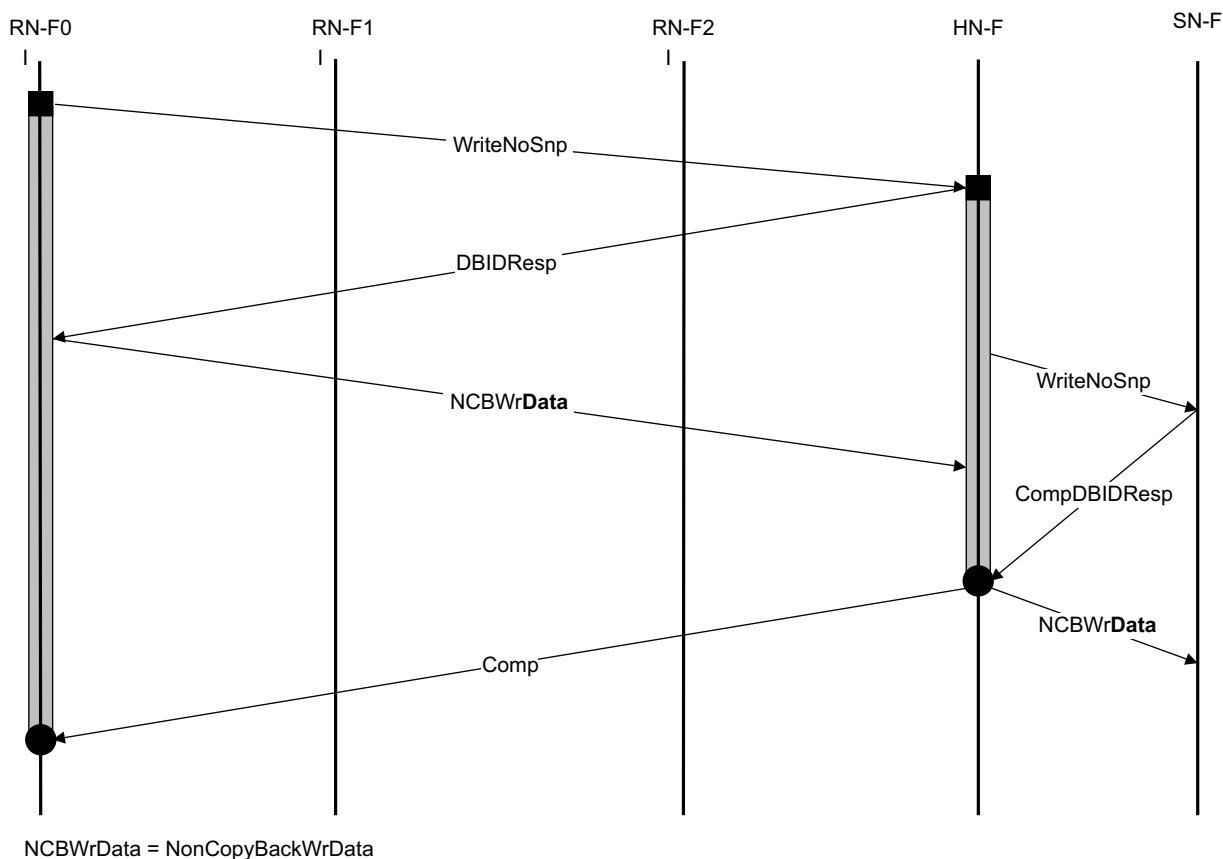

Figure 5-15 WriteNoSnp with separate responses from HN to RN

The steps in the WriteNoSnp transaction flow in Figure 5-15 are:

1. RN-F0 issues a WriteNoSnp transaction to HN-F. HN-F receives and allocates the request.
2. HN-F sends DBIDResp without Comp. Meanwhile, HN-F sends WriteNoSnp to SN-F.
3. RN-F0 responds with data, NCBWrData. SN-F returns CompDBIDResp to HN-F.
4. HN-F sends a Comp after it receives CompDBIDResp from SN-F. HN-F sends NCBWrData to the SN-F.

Note

This flow example shows Comp is sent after CompDBIDResp is received from SN-F. However, HN-F is permitted to send Comp anytime after it receives the WriteNoSnp request from RN-F0.

5. RN-F0 waits for Comp from HN-F and deallocates its request.

Figure 5-15 shows the flow, the copy of data being transferred is marked in bold.

5.3.2 Write transaction with snoop and separate responses

An example of this type of flow is a WriteUniquePtl transaction.

Figure 5-16 shows the transaction flow. The copy of data being transferred is marked in bold.

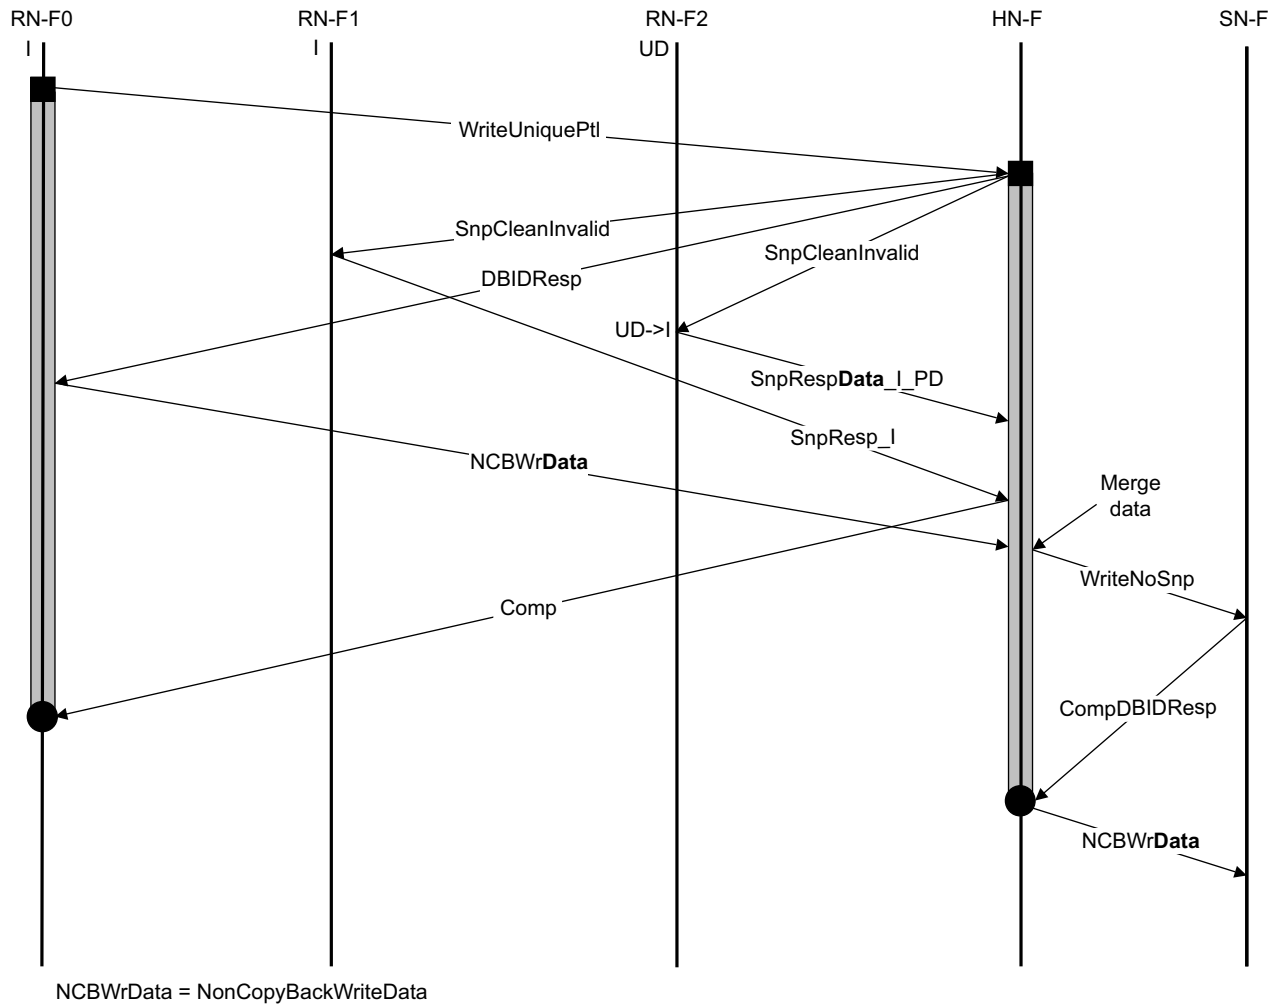

Figure 5-16 WriteUniquePtl with snoop

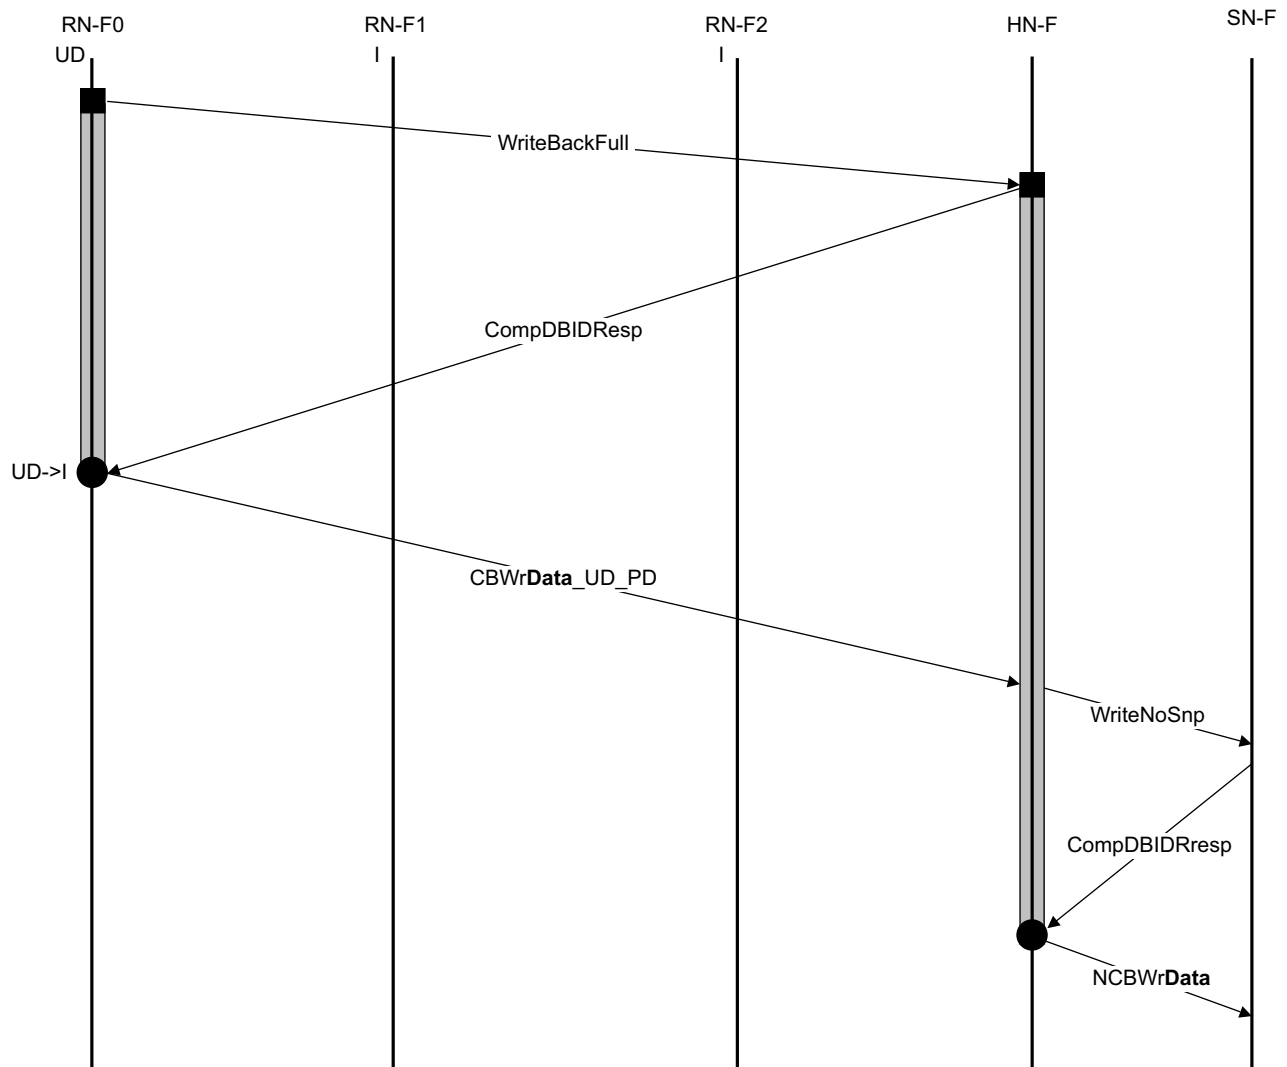

The steps in the WriteUniquePtl with snoop transaction flow in Figure 5-16 are:

1. RN-F0 sends WriteUniquePtl request to HN-F.
2. HN-F sends SnpCleanInvalid requests to RN-F1 and RN-F2. HN-F also returns DBIDResp to RN-F0. RN-F2 cache line state transitions from UD to I.
3. RN-F1 sends SnpResp_I and RN-F2 sends SnpRespData_I_PD to HN-F.
4. RN-F0 issues NCBWrData to HN-F. HN-F merges the write data with the dirty line and sends WriteNoSnp to SN-F.
5. HN-F sends Comp response to RN-F0.
6. SN-F returns CompDBIDResp to HN-F.
7. HN-F sends NCBWrData to SN-F.

5.3.3 CopyBack Write transaction to memory

An example of this type of flow is a WriteBackFull transaction.

Figure 5-17 shows the transaction flow. The copy of data being transferred is marked in bold.

CBWrData = CopyBackWrData
NCBWrData = NonCopyBackWrData

Figure 5-17 WriteBackFull transaction flow

The steps in the WriteBackFull transaction flow in Figure 5-17 are:

1. RN-F0 sends WriteBackFull request to HN-F.
2. HN-F returns CompDBIDResp to RN-F0. RN-F0 cache line state transitions from UD to I.
3. RN-F0 sends CBWrData_UD_PD to HN-F. HN-F sends WriteNoSnp to SN-F.
4. SN-F returns CompDBIDResp to HN-F.
5. HN-F sends NCBWrData to SN-F.

5.4 Atomic transaction flows

This section shows flows for different Atomic transaction types. It contains the following subsections:

- [Atomic transactions with data return](#)
- [Atomic transaction without data return on page 5-276](#)
- [Atomic operation executed at the SN on page 5-278](#)

5.4.1 Atomic transactions with data return

This flow is applicable to:

- AtomicLoad
- AtomicCompare
- AtomicSwap

Atomic transaction with snoops and data return

Figure 5-18 shows the atomic operation executed at HN-F.

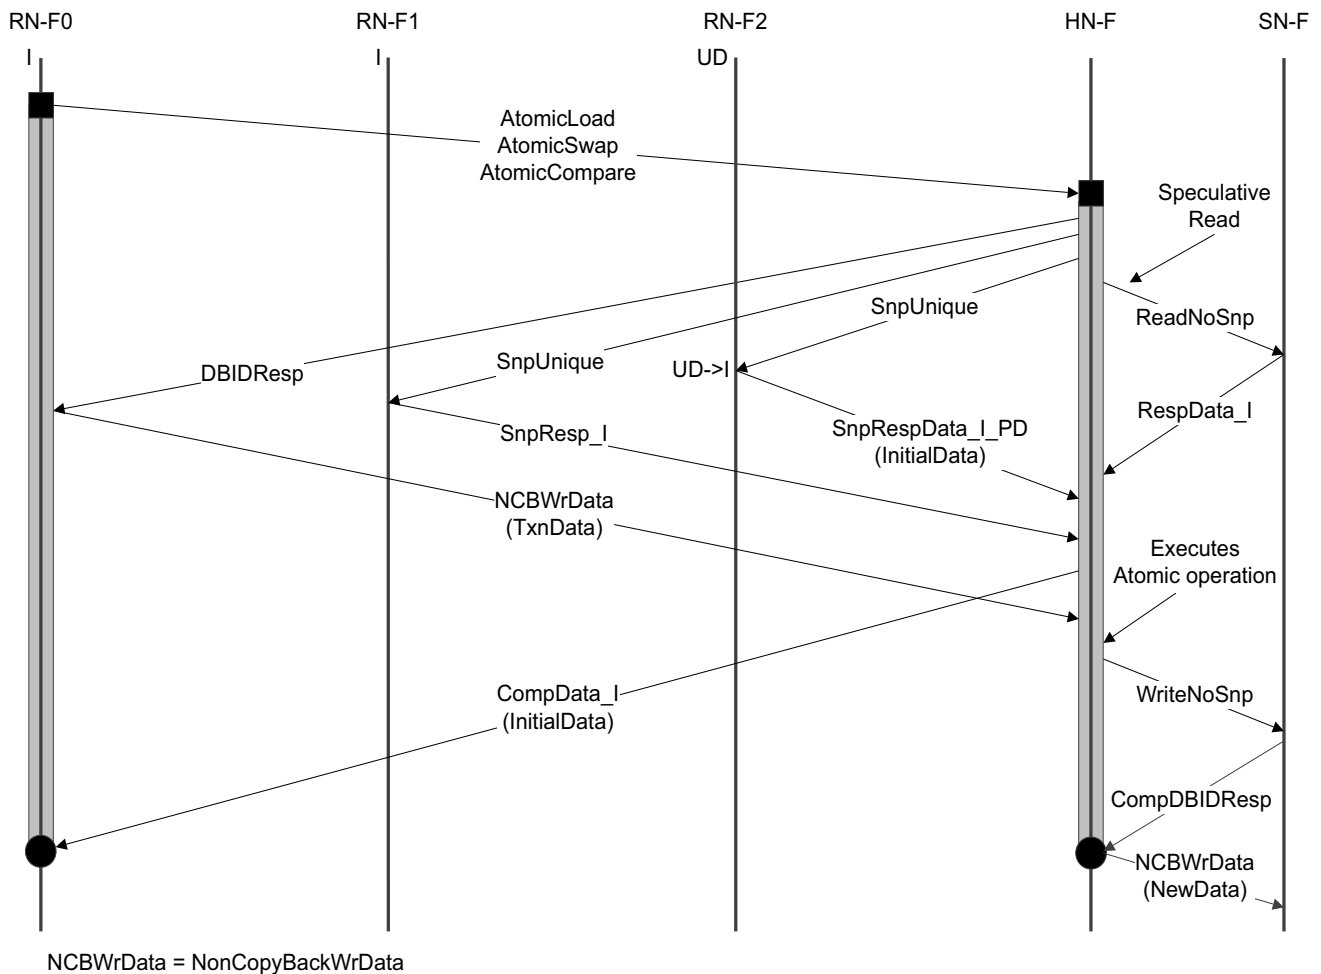

Figure 5-18 AtomicLoad, AtomicSwap, or AtomicCompare executed at HN-F

The steps in Figure 5-18 are:

1. RN-F0 sends an Atomic transaction to HN-F.

2. After receiving the Atomic request, HN-F:
 - Sends DBIDResp to RN-F0 to obtain the Atomic transaction data.
 - Sends SnpUnique Snoop request to other RN-Fs after determining that snoops are required.
 - HN-F is permitted, but not required, to send a speculative ReadNoSnp to SN-F.
3. RN-F2 has the cache line in UD state and responds by sending data and invalidating its own cached copy.
 - The response is SnpRespData_I_PD.
 - This data is marked as (InitialData) in [Figure 5-18 on page 5-273](#) to distinguish it from both the data sent by the Requester and the data written to SN-F after the atomic operation is executed.
 - HN-F also receives a second Snoop response, SnpResp_I, from RN-F1.
4. After receiving all Snoop responses, HN-F sends CompData_I to the Requester.
 - The data sent with Comp is the initial copy of the data.
 - This data must not be cached in a coherent state at RN-F0.
5. In response to the DBIDResp sent previously, HN-F receives the NonCopyBackWrData_I response from the Requester.
 - This data is marked as (TxnData) in [Figure 5-18 on page 5-273](#) to distinguish it from the data sent by RN-F2 in response to the Snoop request from HN-F.
6. Once HN-F receives the NonCopyBackWrData_I response from the Requester, and the Snoop response with data from RN-F2, it executes the atomic operation.
 - The resulting value after atomic operation execution, marked as (NewData) in [Figure 5-18 on page 5-273](#), is written to SN-F.
7. In this example, the read data received due to the speculative read is discarded by HN-F.

———— **Note** ————

In [Figure 5-18 on page 5-273](#), the CompData_I response from HN-F can be sent when all Snoop responses are received.

Alternatively, to aid error reporting, CompData_I can be delayed until NCBWrData is received from the Requester and the atomic operation is executed.

—————

Atomic transaction without snoops and with data return

Figure 5-19 shows the atomic operation executed at the Home Node.

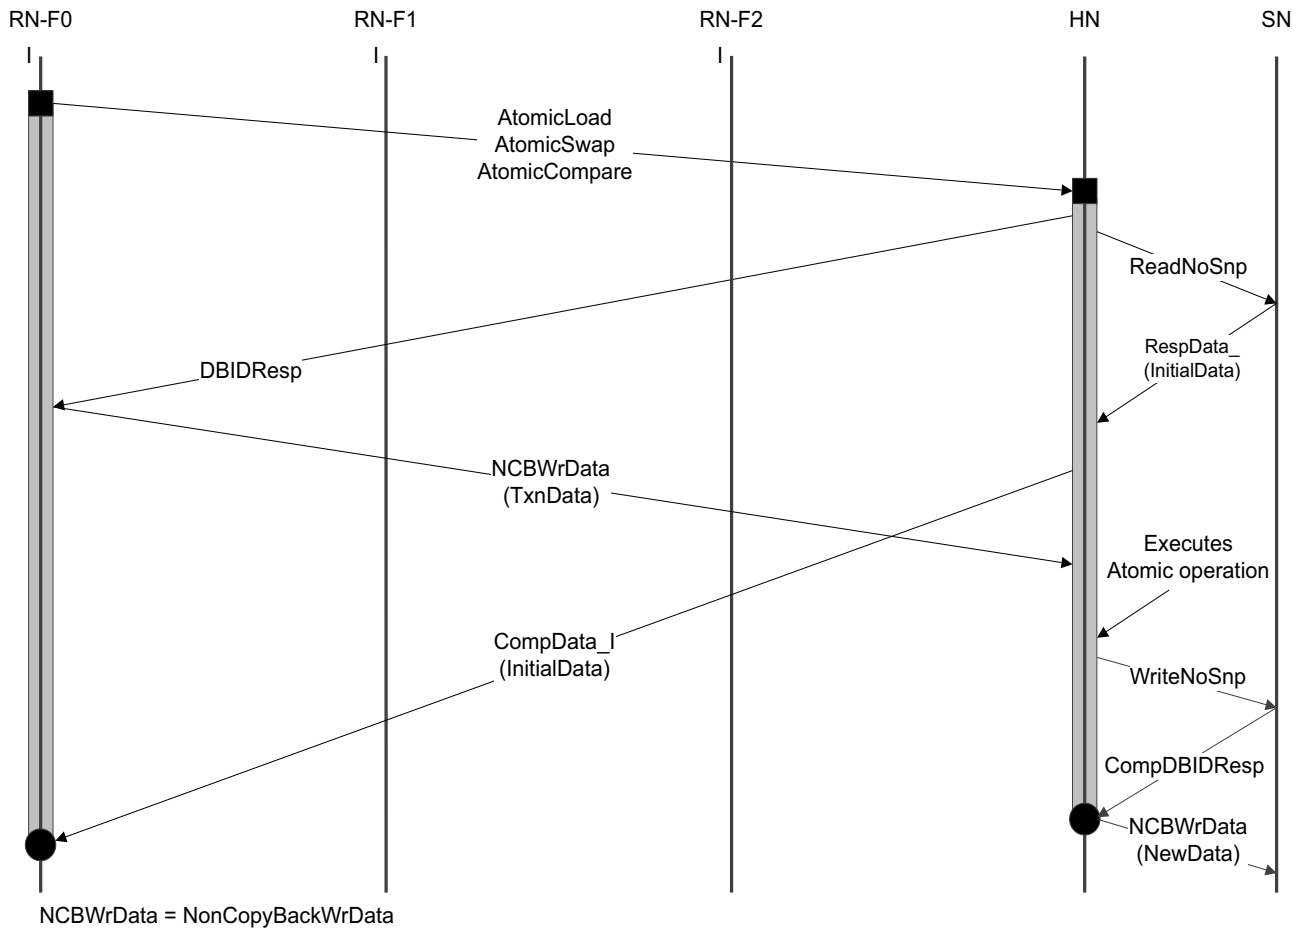

Figure 5-19 AtomicLoad, AtomicSwap, or AtomicCompare executed at HN

The steps in the Atomic transaction executed at the Home Node transaction flow in Figure 5-19 are:

1. RN-F0 sends Atomic transaction request to HN.
2. HN returns DBIDResp to RN-F0.
3. HN sends ReadNoSnp request to SN. Meanwhile, RN sends NCBWrData (TxnData) to HN.
4. SN returns RespData_I (InitialData) to HN.
5. HN returns CompData_I (InitialData).
6. HN executes the Atomic operation and sends WriteNoSnp request to SN.
7. SN returns CompDBIDResp to HN.
8. HN sends the result of the atomic operation to SN, marked as (NewData).

5.4.2 Atomic transaction without data return

This flow is applicable to AtomicStore transactions.

Atomic transaction with snoops and without data return

Figure 5-20 shows the atomic operation executed at HN-F. The flow is similar to the Atomic transaction with snoop and with data return, except that the Comp response to RN-F0 does not include data.

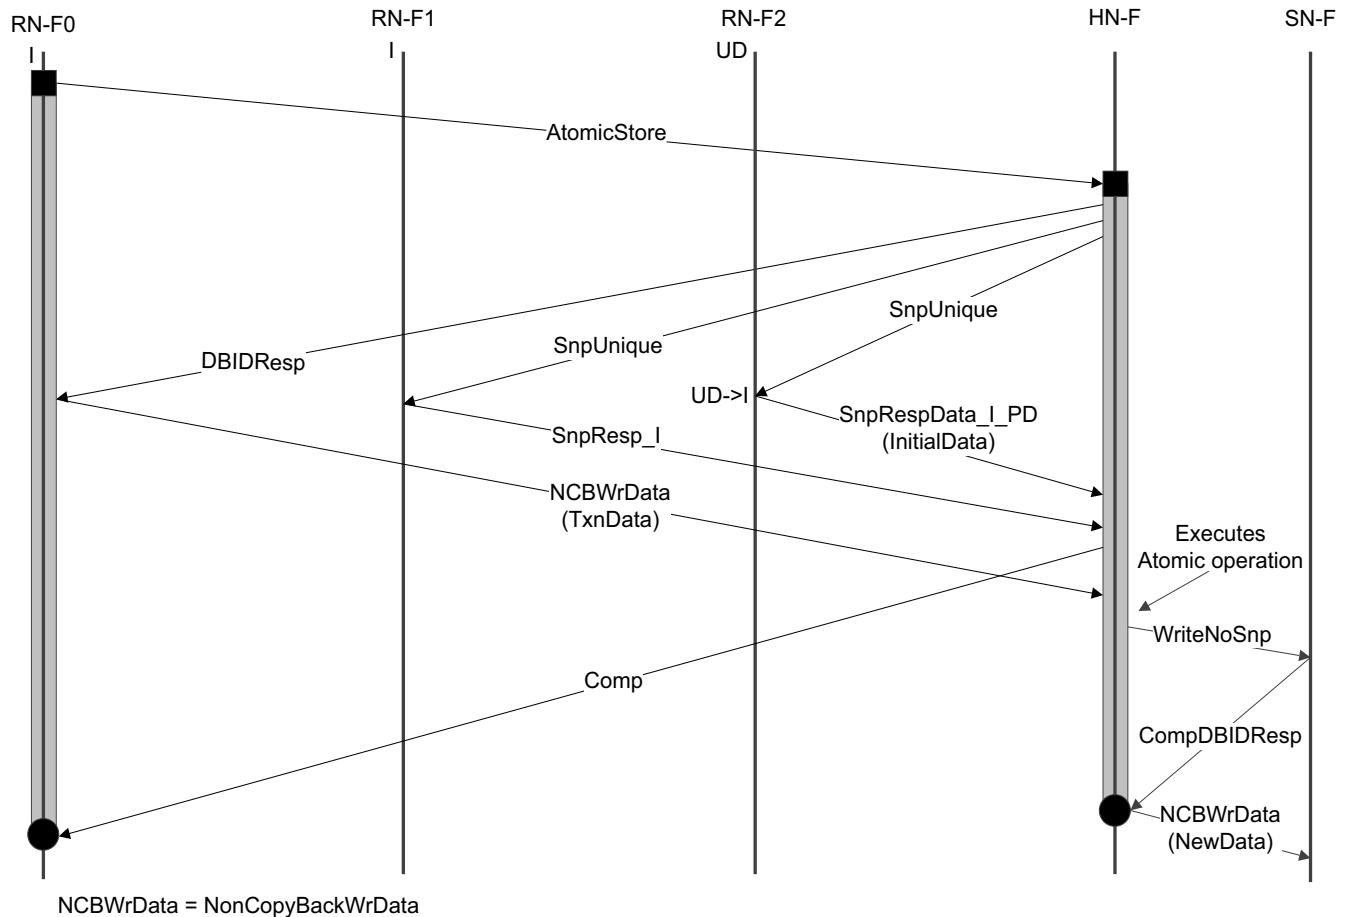

Figure 5-20 AtomicStore executed at HN-F

The steps in the AtomicStore transaction executed at HN in Figure 5-20 are:

1. RN-F0 sends AtomicStore request to the HN-F.
2. HN-F issues DBIDResp to the Requester, RN-F0, and SnpUnique requests to RN-F1 and RN-F2.
3. RN-F1 returns SnpResp_I response to the HN-F. RN-F2 has the cache line in UD state and returns a SnpRespData_I_PD (InitialData) response. This invalidates the cached copy in RN-F2.
4. RN-F0 sends the write data (TxnData) to the HN-F. The HN-F executes the AtomicStore operation locally.
5. HN-F issues a WriteNoSnp request to the SN-F.
6. SN-F returns CompDBIDResp to the Home.
7. HN-F sends the result of the atomic operation to the SN-F, marked as (NewData).

Atomic transaction without snoops and without data return

Figure 5-21 shows the atomic operation executed at the Home Node. The flow is similar to the Atomic transaction without snoop and with data return except that the Comp response to the Request Node does not include data.

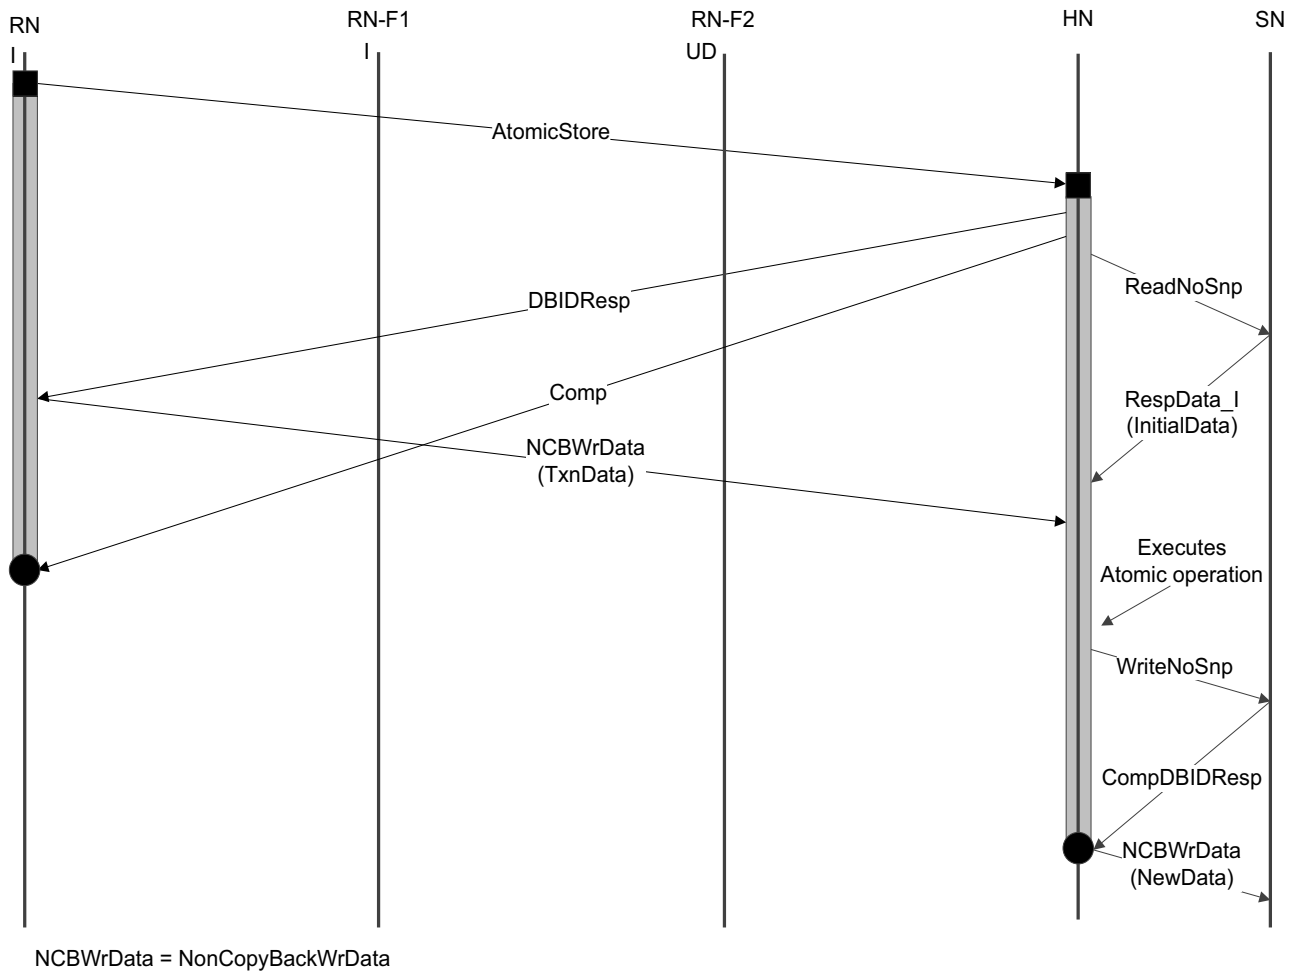

Figure 5-21 AtomicStore executed at HN

————— Note —————

In Figure 5-21, the read from the Subordinate Node is required to obtain the InitialData and is not speculative.

The Comp response from the Home Node can be combined with the DBIDResp response.

The steps in the AtomicStore transaction executed at the HN in Figure 5-21 are:

1. RN sends AtomicStore request to the HN.
2. HN returns DBIDResp response to RN, indicating the RN can send the write data to the HN.
3. HN sends Comp response to RN and sends ReadNoSnp request to the SN.
4. SN returns RespData_I to the HN.
5. Once the HN has the write data from the RN, it can execute the atomic operation and send WriteNoSnp to SN.
6. SN returns CompDBIDResp to the HN.
7. HN sends the result of the atomic operation to the SN, marked as NewData.

5.4.3 Atomic operation executed at the SN

Figure 5-22 shows an example Atomic transaction flow where the SN-F is executing the atomic operation.

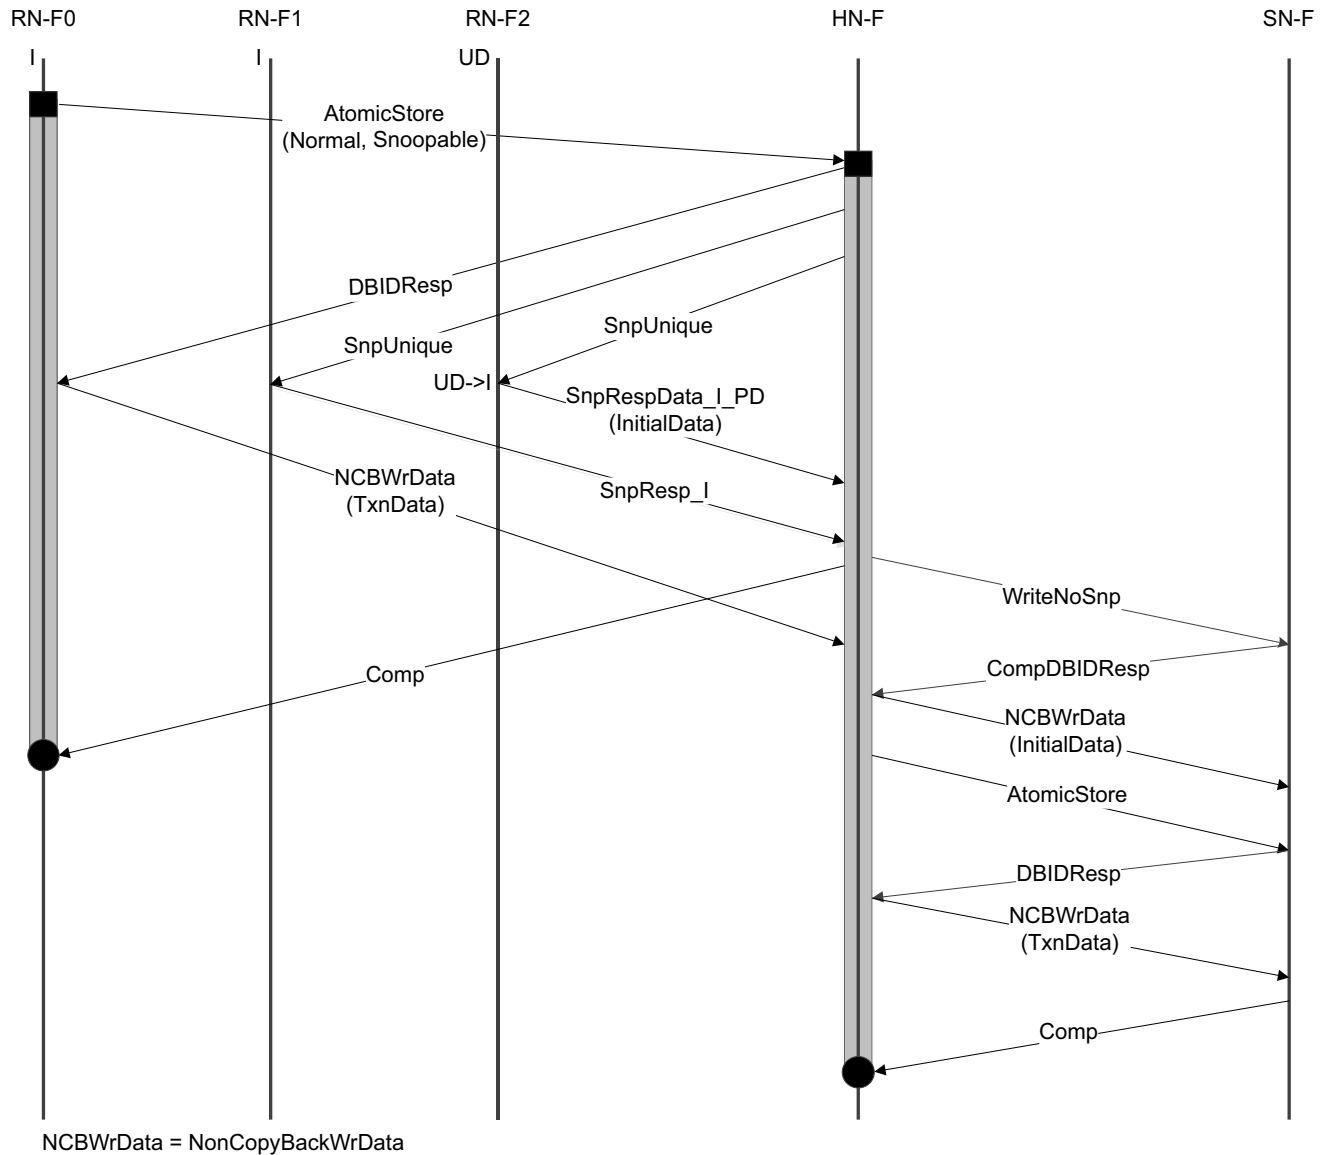

Figure 5-22 AtomicStore executed at SN-F

The steps in the AtomicStore transaction executed at SN-F in Figure 5-22 are:

1. RN-F0 sends an AtomicStore transaction to HN-F.
 - The Atomic request is to a Snoopable address location.
2. After receiving the Atomic request, HN-F:
 - Sends DBIDResp to RN-F0 to obtain the Atomic transaction data.
 - Sends a SnpUnique to other RN-Fs after determining that snoops are required.
3. RN-F2 has the cache line in UD state and responds by sending data and invalidating its own cached copy.
 - The response is SnpRespData_I_PD.
 - This data is marked as (InitialData) in Figure 5-22 to distinguish it from both the data sent by the Requester and the data written to SN-F to execute the atomic operation.

- HN-F also receives a second Snoop response, SnpResp_I, from the other snooped RN-F.
4. HN-F writes the received data to SN-F using a WriteNoSnp transaction.
 5. In response to the DBIDResp sent previously, HN-F receives the NonCopyBackWrData response from the Requester.
 6. HN-F after sending the Snoop response data to SN-F, sends an AtomicStore transaction request to SN-F, and executes the sequence of messages required to complete the Atomic transaction.
 7. The HN-F deallocates the request once the Comp response is sent to the Requester and the Comp response for the Atomic transaction is received from SN-F.
 - The Comp response from HN-F can be sent when all the Snoop responses are received.

5.5 Stash transaction flows

This section shows example interconnect protocol flows for the two Stash transaction types:

- [Write with Stash hint](#)
- [Independent Stash request on page 5-282](#)

5.5.1 Write with Stash hint

Figure 5-23 shows an example WriteUniqueStash with Data Pull transaction flow.

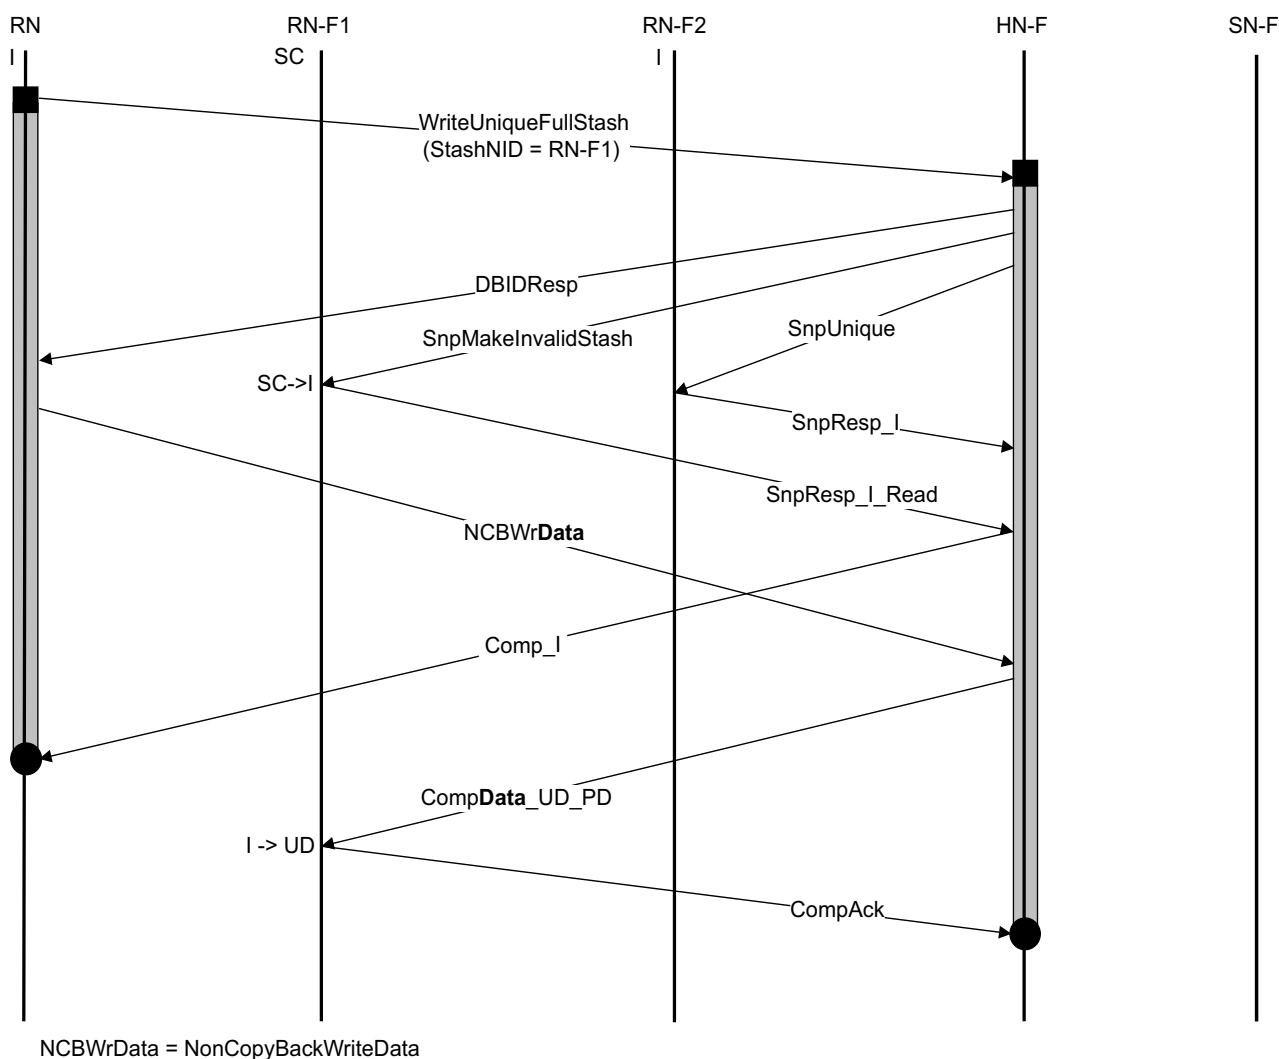

Figure 5-23 WriteUniqueStash with Data Pull

The steps in Figure 5-23 are:

1. The Request Node sends a WriteUniqueFullStash request to HN-F with the Stash target identified as RN-F1. Typically, the requesting Request Node is an RN-I.
2. HN-F sends SnpMakeInvalidStash to RN-F1 and SnpUnique to RN-F2.
3. RN-F1 and RN-F2 send SnpResp response to HN-F. The Snoop response from RN-F1 also includes a Read request, that is, the Data Pull.

4. HN-F treats the Read request from RN-F1 as a ReadUnique, and sends a combined CompData to RN-F1. CompData response includes the data written by the Request Node.
5. RN-F1 sends CompAck to HN-F to complete the Read transaction.

5.5.2 Independent Stash request

Figure 5-24 shows an example StashOnce with Data Pull transaction flow.

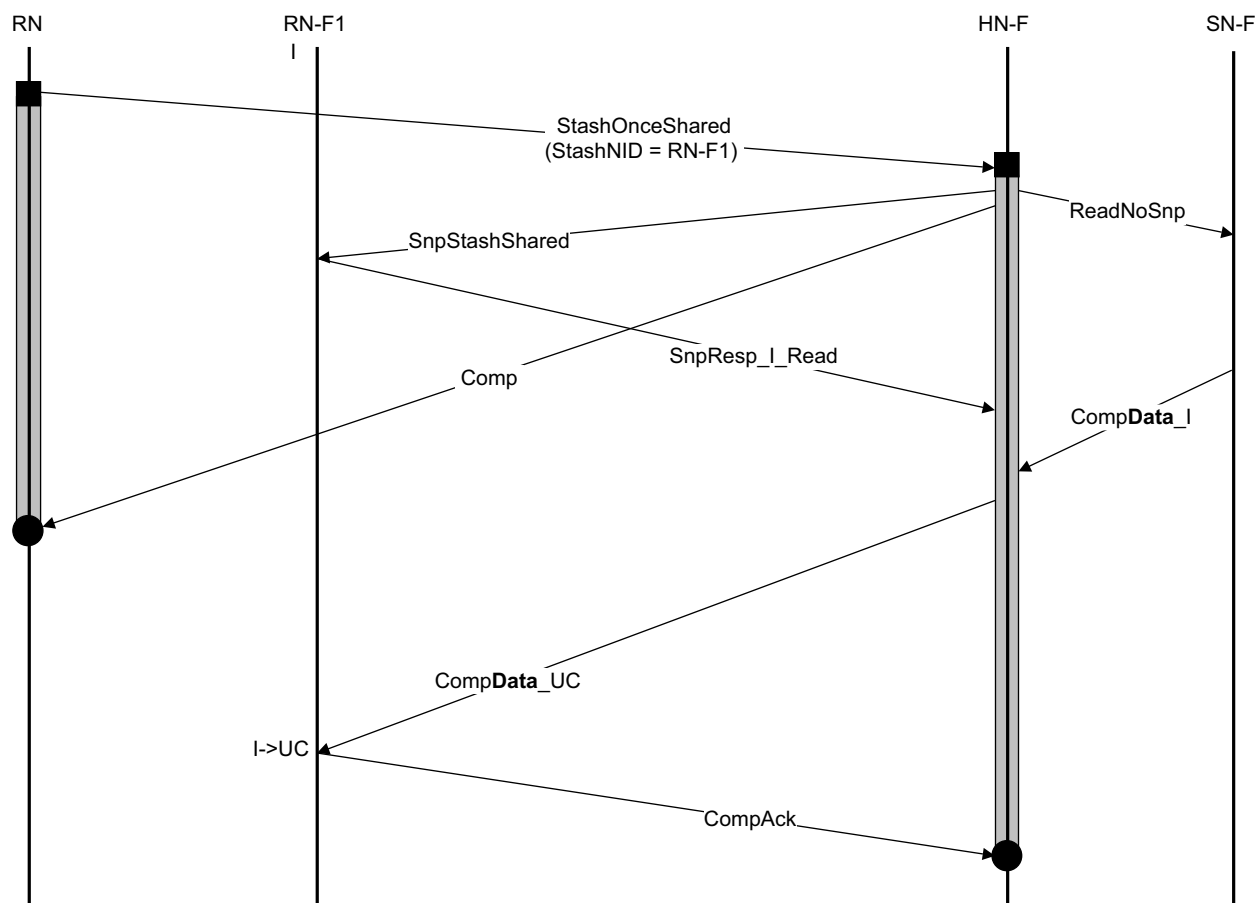

Figure 5-24 StashOnceShared with Data Pull

The steps in Figure 5-24 are:

1. The Request Node sends a StashOnceShared request to HN-F with the Stash target identified as RN-F1.
2. HN-F sends a Comp response after establishing processing order for the received request that is guaranteeing the request is processed before a request to the same address received later from any Requester.
3. HN-F sends a SnpStashShared snoop to RN-F1, and a ReadNoSnp request to SN-F to fetch data.
4. RN-F1 sends SnpResp_I_Read response to HN-F.
5. HN-F treats the Read request from RN-F1 as a ReadNotSharedDirty, and sends a combined CompData to RN-F1.
6. RN-F1 sends CompAck to HN-F to complete the Read transaction.

5.6 Hazard handling examples

This section shows how CopyBack-Snoop request hazard conditions are handled at the Requester, and how various requests to request and request to snoop request hazard conditions are handled at the HN-F. It contains the following subsections:

- [CopyBack-Snoop hazard at RN-F](#)
- [Request hazard at HN-F on page 5-286](#)
- [Read - CopyBack or Dataless - CopyBack hazard at HN-F on page 5-288](#)
- [HN-F race hazard: Request and CompAck on page 5-289](#)

5.6.1 CopyBack-Snoop hazard at RN-F

Figure 5-25 shows a Snoop request to an RN-F hazarding a pending CopyBack request at Time C.

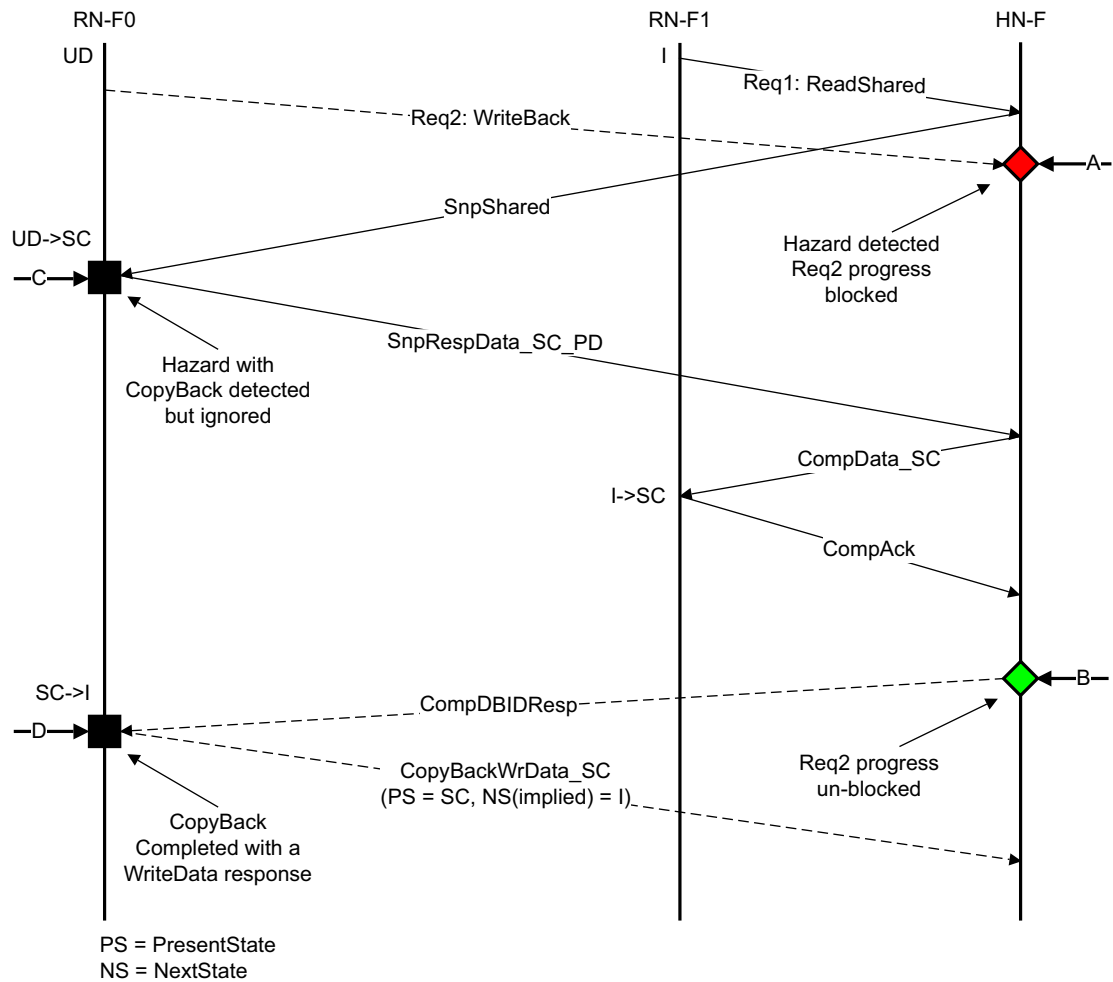

Figure 5-25 CopyBack-Snoop hazard at RN-F example

The steps required to resolve this hazard are:

- At Time C:
 - The SnpShared transaction ignores the hazard and reads the cache line data.
 - The cache line state is changed from UD to SC.

2. At Time D:
 - The CompDBIDResp for the CopyBack is sent to RN-F0.
 - RN-F0 sends back a CopyBackWrData_SC response.
 - The cache line state is changed from SC to I.

The data is clean for coherence and is not required to be sent to the interconnect for correct functionality. However, the protocol requires the CopyBack flow to be consistent irrespective of a snoop hazard.

The cache line state in the WriteData response is SC because that is the state of the cache line when the WriteData response is sent.

Note

- The response to a Snoop request that hazards with an outstanding Evict must be SnpResp_I.
 - The only response that can be received for a CopyBack request, while a Snoop response to a Snoop request to the same address is pending, is a RetryAck. This includes data, if applicable.
-

Figure 5-26 on page 5-285 shows a further example of a Snoop request hazarding with an outstanding CopyBack request. In this example, the Snoop request is a SnpOnce request generated as a result of a ReadOnce request from RN-F1. The SnpOnce request receives a copy of the data with the Snoop response but does not change the cache line state. In this case, the final data response from RN-F0 indicates that the data is Dirty and that HN-F must write the data back to memory.

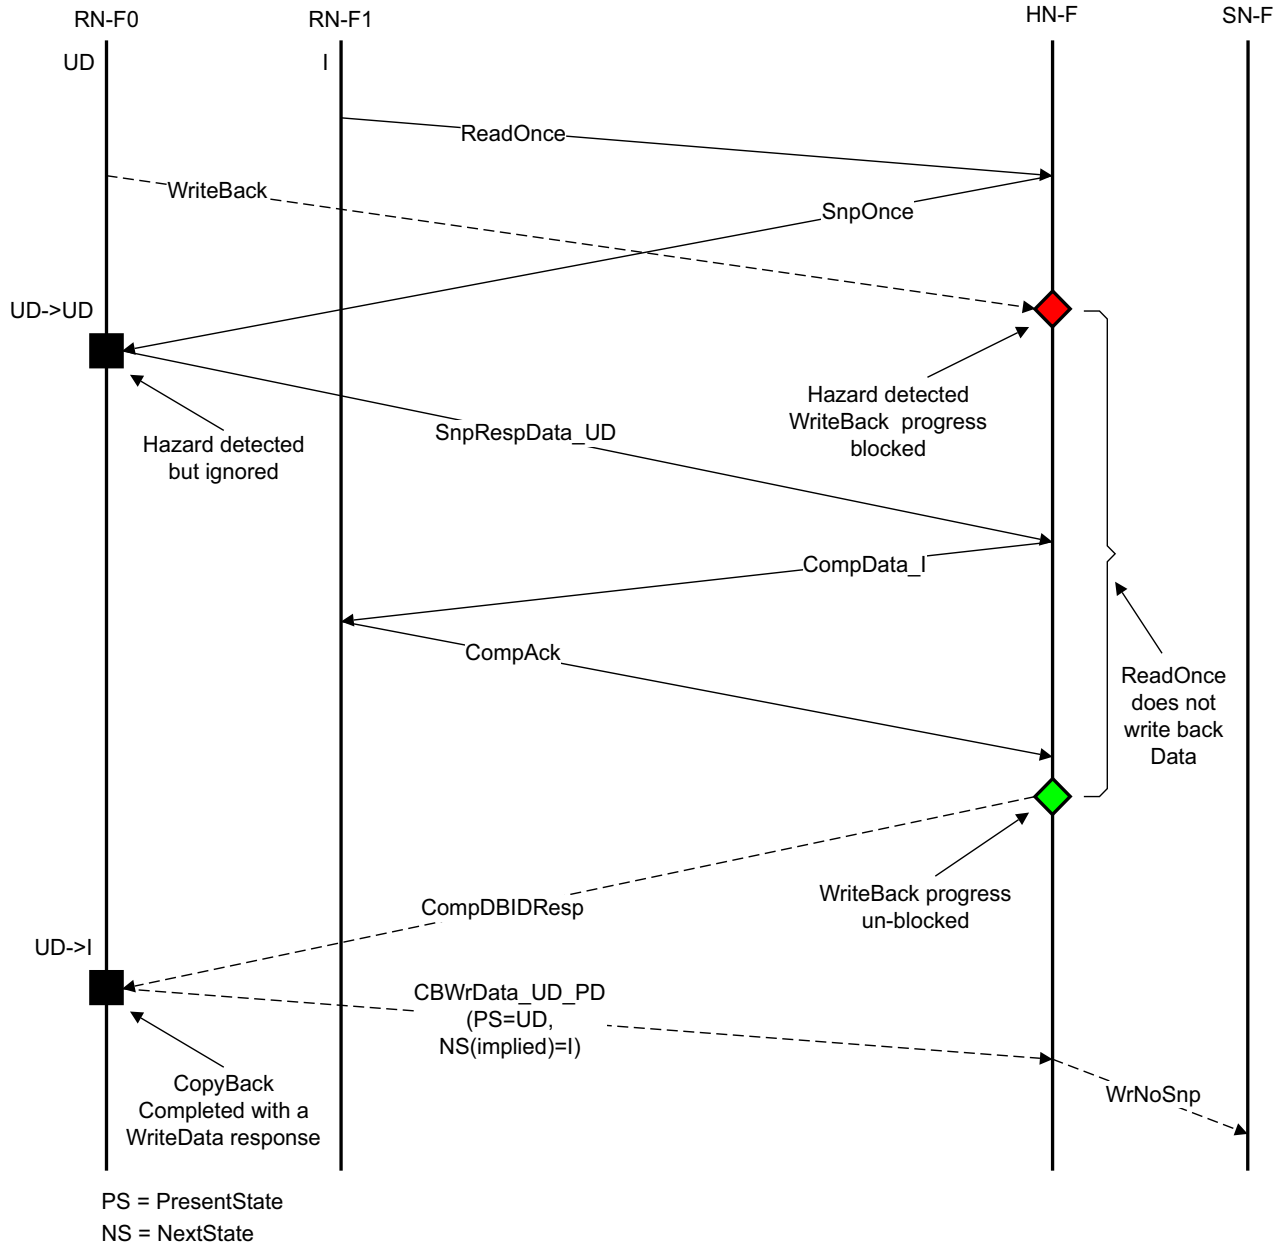

Figure 5-26 CopyBack-Snoop hazard with no cache state change example

5.6.2 Request hazard at HN-F

If more than one request to the same cache line is ready to be processed at the HN-F, then the HN-F can select the next request in any order. The exception for this is when the two requests have an ordering requirement and are from the same source, then the order of processing must match the order of arrival.

Figure 5-27 shows an example where a ReadShared and a ReadUnique, for the same cache line, arrive at the HN-F at approximately the same time.

Figure 5-27 Read-Read request hazard example

The steps required to resolve this hazard in Figure 5-27 are:

1. At Time A:
 - ReadUnique from RN-F0 arrives and hazards a ReadShared request from RN-F2 for which the HN-F has already sent Snoop requests.
 - ReadUnique progress is blocked at the HN-F.
2. At Time B:
 - The HN-F has completed the ReadShared transaction request from RN-F2.

- The ReadShared transaction is considered to be complete and the HN-F unblocks the ReadUnique transaction request from RN-F0.

Except for ReadNoSnP, the flows are similar if the two transactions, that [Figure 5-27 on page 5-286](#) shows, are replaced by any Read request type, or Dataless request type:

- A Read transaction request without DMT or DCT or separate Comp and data response is completed at the HN-F when both of the following are true:
 - All CompData is sent and, if applicable, CompAck is received. A CompAck is only required for transactions that assert ExpCompAck in the original request message.
 - A memory update is completed if required.

5.6.3 Read - CopyBack or Dataless - CopyBack hazard at HN-F

A hazard between a Read or Dataless request and a CopyBack request at the HN-F is treated similarly to the Read-Read hazard described in [Request hazard at HN-F on page 5-286](#). See also [CopyBack-Snoop hazard at RN-F on page 5-283](#).

[Figure 5-28](#) shows the case where a ReadShared and a WriteBack, for the same cache line, arrive at the HN-F at approximately the same time.

Figure 5-28 Read - CopyBack or Dataless - CopyBack hazard example

The steps required to resolve this hazard in [Figure 5-28](#) are:

1. At Time A:
 - A WriteBack encounters a hazard condition at the HN-F. The reason for the hazard is a ReadShared transaction that is already in progress.
 - The hazard detection results in the WriteBack being blocked.
 - The ReadShared transaction receives data with the snoop response and must update memory in addition to sending the data to the Requester.
2. At Time B:
 - The WriteBack is unblocked because the HN-F has sent the data response to the Requester and a WriteData response to memory for the ReadShared transaction.

If the ReadShared request reaches the HN-F, after the HN-F has started processing the WriteBack request, then the ReadShared request will be blocked until completion of the WriteBack request.

A CopyBack request is completed at HN-F when both of the following are true:

- A data message corresponding to the CopyBack request is received.
- A memory update is completed if necessary.

5.6.4 HN-F race hazard: Request and CompAck

After completion, a request might silently evict the cache line from the cache and generate another request to the same address. For example:

1. The regenerated request reaches the HN-F before the CompAck response associated with the earlier request.
2. The HN-F detects an address hazard and blocks the processing of the new request until the CompAck response is received.

In such a scenario, on arrival at HN-F, the CompAck response deallocates the previous request from the HN-F and unblocks the processing of the new request.

Chapter 6

Exclusive accesses

This chapter describes the mechanisms that the architecture includes to support Exclusive accesses. It contains the following sections:

- [Overview on page 6-292](#)
- [Exclusive monitors on page 6-293](#)
- [Exclusive transactions on page 6-296](#)

6.1 Overview

The principles of Exclusive accesses are that a *Logical Processor* (LP) performing an exclusive sequence does the following:

- Performs an Exclusive Load from a location.
- Calculates a value to store to that location.
- Performs an Exclusive Store to the location.

Exclusive accesses are supported to Snoopable and Non-snoopable memory locations.

If the location is updated by a different LP since the Exclusive Load, the Exclusive Store must fail. In this case, the store does not occur and the LP does not update the value held at the location.

Table 6-1 shows the descriptions for Exclusive terms.

Table 6-1 Description of Exclusive terms

Term	Description of Exclusive terms
Exclusive Load	The action of an LP executing an appropriate program instruction, such as LDREX, requires: <ul style="list-style-type: none">• Obtaining the data from the location to which it wants to perform an exclusive sequence.• Indicating that it is starting an exclusive sequence.
Exclusive Load transaction	A transaction issued on the interface to obtain data for an Exclusive Load, if the data is not available in the cache at the LP. Not every Exclusive Load requires an Exclusive Load transaction.
Exclusive Store	The action of an LP executing an appropriate program instruction, such as STREX, requires: <ul style="list-style-type: none">• Determining if the exclusive sequence has passed or failed.• If appropriate, updating the data at the location. Can pass or fail and this result is known to the executing processor. When an Exclusive Store passes, the data value at the address location is updated. When an Exclusive Store fails, this indicates that the data value at the address location has not been updated, and the exclusive sequence must be restarted.
Exclusive Store transaction	A transaction issued on the interface that might be required to complete an Exclusive Store. Not every Exclusive Store requires an Exclusive Store transaction. An Exclusive Store transaction can pass or fail and this result is made known to the LP using the transaction response.

6.2 Exclusive monitors

The progress of an exclusive sequence is tracked by an exclusive monitor. The location of the monitor and the request type generated to support the Exclusive accesses depends on the memory attributes of the address.

The attributes of Exclusive accesses must be such that they are guaranteed to be observed by an exclusive monitor. For example, if there is a cache between the Requester and monitor, then the Exclusive accesses should be Non-cacheable.

6.2.1 Snoopable memory location

For a Snoopable memory location two monitors are defined:

LP monitor Each LP within an RN-F must implement an exclusive monitor that observes the location used by an exclusive sequence. The LP monitor is set when the LP executes an Exclusive Load. The LP monitor is reset when either:

- The location is updated by another LP, indicated by an Invalidating snoop request to the same address.
- There is a store to the location by the same LP. If the store from the same LP is Non-exclusive, resetting the monitor is IMPLEMENTATION DEFINED.

PoC monitor An HN-F must implement a PoC monitor that can pass or fail an Exclusive Store transaction. A pass indicates that the transaction has been propagated to other coherent RN-Fs. A fail indicates that the transaction has not been propagated to other coherent RN-Fs and the Exclusive Store cannot pass.

The monitor is used to ensure an Exclusive Store transaction from an LP is only successful if the LP could not have received a snoop transaction relating to an Exclusive Store to the same address from another LP, after it issued its own Exclusive Store transaction.

The minimum requirement of the PoC monitor is to record when any LP performs a Snoopable transaction related to an exclusive sequence.

If an LP has performed a transaction related to an exclusive sequence, and it then performs an Exclusive Store transaction before a successful Exclusive Store transaction from another LP is scheduled, then the Exclusive Store transaction must be successful.

The monitor must support the parallel monitoring of all exclusive-capable Logical Processors in the system.

When the HN-F receives a transaction associated with an Exclusive Load or an Exclusive Store, the monitor registers that the LP is attempting an exclusive sequence.

When the HN-F receives an Exclusive Store transaction:

- If the PoC monitor has registered that the LP is performing an exclusive sequence, that is, it has not been reset by an Exclusive Store transaction from another LP, the Exclusive Store transaction is successful and is permitted to proceed. In such a case, registered attempts of all other LPs must be reset. It is recommended, but not required, that the PoC monitor for the successful LP is left as registered.
- If the PoC monitor has not registered that the LP is performing an exclusive sequence, that is, it has been reset by an Exclusive Store from another LP, the Exclusive Store transaction is failed and is not permitted to proceed. The monitor must register that the LP is attempting an Exclusive sequence.

———— Note ————

A successful Exclusive Store transaction from an LP does not have to reset that the LP is performing an exclusive sequence. The LP can continue to perform a sequence of Exclusive Store transactions, which will all be successful, until another LP performs a successful Exclusive Store transaction. For store transactions in which the LP is not identifiable, the store must be handled as from a different LP than the one which set the monitor.

From initial system reset, the first LP to perform an Exclusive Store transaction can be successful. At that point, all other LPs must then register the start of their exclusive sequence for their Exclusive Store transaction to be successful.

When an Exclusive Store transaction from one LP passes and the registered attempts of all other LPs is reset, the other LPs can only register a new exclusive sequence after the CompAck response is observed for the Exclusive Store transaction that passed.

Note

An LP and PoC monitor pair are required to support an Exclusive access to a Snoopable memory location.

6.2.2 Additional address comparison

The PoC monitor can be enhanced to include some address comparison. A full address comparison is not required and it is permitted to only record a subset of address bits. This approach reduces the chances of an Exclusive Store transaction failing because of an Exclusive Store transaction from another Logical Processor to a different address location. The number of bits of address comparison used is IMPLEMENTATION DEFINED.

Where an additional address comparison monitor is used, the monitored address bits are recorded at the start of an exclusive sequence on either a Load Exclusive or Store Exclusive transaction. It is reset by a successful Exclusive Store transaction from another LP to a matching address.

A monitor that includes an additional address comparison must still include a minimum monitor of a single bit for every Exclusive-capable LP to ensure forward progress.

An Exclusive Store transaction is permitted to progress if one of the following occurs:

- The address monitor has registered an exclusive sequence for a matching address from the same LP and has not been reset by an Exclusive Store transaction from a different LP with a matching address.
- The minimum single-bit monitor has been set by an exclusive sequence from the same LP, and it has not been reset by an Exclusive Store transaction from a different LP to any address.

Note

The term ‘matching address’ is used to describe where a monitor only records a subset of address bits. The address bits that are recorded are identical, but the address bits that are not recorded can be different.

An implementation does not require an address monitor for each Exclusive-capable LP. Because the address monitor provides a performance enhancement, it is acceptable to have fewer address monitors and for the use of these to be IMPLEMENTATION DEFINED. For example, address monitors can be used on a first-come first-served basis, or by allocation to particular Logical Processors. Alternatively, a more complex algorithm might be implemented.

Additional PoC exclusive monitor functionality can be provided to prevent interference, or denial of service, caused by one agent in the system issuing many Exclusive access transactions. It is recommended that Secure Exclusive accesses are permitted to make forward progress independently of the progress of Non-secure accesses.

6.2.3 Alternatives to a PoC monitor

An HN-F is permitted to use the following mechanisms instead of a PoC monitor to determine the results of an Exclusive access:

- A precise Snoop Filter, to track if the Requester at the time of Exclusive Store processing retains a copy of the cache line.
- Snooping by the Home Node, to determine if the Requester still holds a copy of the cache line.

Note

Prior to CHI Issue E, a Home Node that supports Exclusive accesses was required to implement a PoC monitor.

6.2.4 Non-snooperable memory location

For a Non-snooperable memory location, a single monitor is used:

System monitor

The System monitor tracks Exclusive accesses to a Non-snooperable region. This monitor type is set by a ReadNoSnp(Excl) transaction and reset by an update to the location by another LP.

System monitors can be placed at a PoS or at endpoint devices. Potentially, the number of devices in the system is much larger than the number of PoS and placing System monitors at a PoS can:

- Reduce System monitor duplication.
- Reduce the time taken for the system to detect failure of an Exclusive access.

A System monitor must be located so it can observe all transactions to the monitored location.

6.3 Exclusive transactions

The following transaction types support Exclusive accesses through an Excl bit:

- Exclusive Load transaction to a Snoopable location:
 - ReadClean
 - ReadNotSharedDirty
 - ReadShared
 - ReadPreferUnique
- Exclusive Store transaction to a Snoopable location:
 - CleanUnique
 - MakeReadUnique
- Exclusive Load transaction to a Non-snoopable location:
 - ReadNoSnp
- Exclusive Store transaction to a Non-snoopable location:
 - WriteNoSnp

The communicating node pairs are:

- For Exclusives to a Snoopable location:
 - RN-F to ICN(HN-F).
- For Exclusives to a Non-snoopable location:
 - RN-F, RN-D, RN-I to ICN(HN-F, HN-I).
 - ICN(HN-F) to SN-F.
 - ICN(HN-I) to SN-I.

An exclusive transaction must use the correct LPID value, See [Logical Processor Identifier, LPID on page 13-426](#).

6.3.1 Responses to exclusive requests

Transaction responses to exclusive requests are similar to the normal responses to reads and writes with the following exceptions:

- ReadClean, ReadNotSharedDirty, and ReadShared Exclusive transactions:
 - Must not use separate Comp and data response.
 - Requests that do not fail must not use either DMT or DCT.
- ReadNoSnp Exclusive transactions that do not fail, must not use DMT.
- WriteNoSnpFull and WriteNoSnpPtl transactions, must not use DWT if the Exclusive monitor is located at the Home and the Exclusive check passes.

However, the response for the following Exclusive transactions must also indicate if the exclusive request has passed or failed:

- ReadClean
- ReadNotSharedDirty
- ReadShared
- ReadNoSnp
- CleanUnique
- WriteNoSnpFull
- WriteNoSnpPtl

The RespErr field in the response is used for this purpose. See [Response Error, RespErr on page 13-447](#). The RespErr field value of 0b01, Exclusive Okay, indicates a pass and a RespErr field value of 0b00, Normal Okay, indicates an Exclusive access failure.

The Exclusive Okay response must only be given for a transaction that has the Excl attribute set.

Not all memory locations are required to support Exclusive accesses. An Exclusive Load transaction to a location that does not support Exclusive accesses must not be given an Exclusive Okay response.

It is IMPLEMENTATION DEFINED whether or not Exclusive Store transaction to a location that does not support Exclusive accesses will update the location.

It is recommended that an Exclusive Store transaction is not performed to a location that does not support Exclusive accesses.

ReadPreferUnique and MakeReadUnique do not use RespErr to determine the pass or fail of an Exclusive operation. An Exclusive MakeReadUnique response with Shared cache state indicates the failure of an Exclusive access. When the response cache state is Unique, the Requester must use its Local Monitor state to determine if the Exclusive access is a pass.

Table 6-2 shows the Snoopable attributes of the request, the relevant monitor type and possible reasons for fail conditions and response requirements.

Table 6-2 Responses to an Exclusive access request

Request type	Snoopable	Monitor type	Fail condition	Response
ReadNoSnp(Excl)	No	System	Target does not support Exclusive accesses	Target must return a data response
WriteNoSnp(Excl)	No	System	Address content modified	The Requester must still complete the write flow by sending the Data message
			Address not present due to monitor overflow	
			Target does not support Exclusive accesses	
ReadClean(Excl) ReadNotSharedDirty(Excl) ReadShared(Excl)	Yes	LP, PoC	Target does not support Exclusive accesses	Target must return a data response
ReadPreferUnique	Yes	LP, Optional PoC	None	If a PoC monitor is available, the appropriate monitor bit must be set
CleanUnique(Excl)	Yes	LP, PoC	Address content modified	Target must return a Comp response
			Address not present due to monitor overflow	
			Target does not support Exclusive accesses	
MakeReadUnique(Excl)	Yes	LP, Optional PoC	Address content modified	Target uses PoC monitor, Precise snoop filter, or SnpQuery to determine response

MakeReadUnique(Excl)

When performing an Exclusive Store operation, MakeReadUnique(Excl) is the preferred alternative over the CleanUnique(Excl) request.

The permitted responses to the MakeReadUnique(Excl) request are included in [Table 4-37 on page 4-227](#) and [Table 4-38 on page 4-228](#).

Result of an Exclusive access

The result of an Exclusive access is determined in the following manner:

- RespErr value of Exclusive Okay is not permitted in response to a MakeReadUnique(Excl).
- The Requester must use its local exclusive monitor along with the cache state in the response to determine the success of an Exclusive Store.
 - When the cache state in the response is Shared, the Requester must assume that the Exclusive access has failed.
 - When the cache state in the response is Unique, the Requester must use its own local monitor to determine the result of the Exclusive access.

Home behavior

If the Home, after checking the PoC monitor, determines the Exclusive Store passes, it must invalidate all other cached copies of the cache line and then send a Comp response with the cache state of Unique to the Requester. The cache state can include [_PD] if a cached copy in SD state was invalidated and the responsibility of writing back of the Dirty data is being passed to the Requester.

To avoid an Exclusive access livelock, the monitor must be capable of simultaneously tracking each individual LP Exclusive thread in the system.

A Home is permitted to use a precise Snoop Filter to determine the success or failure of an Exclusive access. If the Snoop Filter indicates that the Requester has lost the cache line, it must be assumed that the Exclusive access has failed.

In the absence of precise caching information from the Snoop Filter, the Home can use the SnpQuery snoop to determine the presence and state of the cache line at the Requester.

When a Home determines that an Exclusive Store transaction has failed, the following rules must be followed:

- If the Requester has lost the cache line, the Home is expected to send SnpPreferUniqueFwd or SnpPreferUnique to get a copy of the cache line. The Home is permitted to send SnpNotSharedDirty(Fwd), or SnpClean(Fwd), or SnpShared instead. The snoop must not be SnpSharedFwd nor any Invalidating snoop.
- The sender of the data is permitted to return, as appropriate, a UC or UD state in the response to the Requester if no other cached copies exist.

The Completer must return data with SC state, if other copies exist.

SD state is not permitted in the response to the Requester. This is because the Home cannot determine from the MakeReadUnique(Excl) request whether the Requester will accept data in SD state.

Data is provided in response to a MakeReadUnique(Excl) transaction when a cache line is lost to a snoop between the issuing of the MakeReadUnique(Excl) transaction and the point at which the Home actions the transaction or the Home cannot determine that the data has been retained.

6.3.2 System responsibilities

A system that implements the CHI protocol has the following responsibilities:

- Should include a monitor per LP for the efficient handling of Exclusive accesses.
- Must have a starvation prevention mechanism for all exclusive requests, whether using the monitor mechanism or some other means.

- It is recommended that progress on Secure exclusive requests is independent of progress on Non-secure Exclusive requests.

6.3.3 Exclusive accesses to Snoopable locations

This section describes the behavior of an LP when performing Exclusive accesses to a Snoopable address location.

Snoopable Exclusive Load

The LP starts an exclusive sequence with an Exclusive Load. The start of the exclusive sequence must set the LP exclusive monitor.

An LP wanting to perform an Exclusive access to a Snoopable location might already hold the cache line in its local cache:

- If the LP holds the cache line in a Unique state, it is permitted, but not recommended, that it performs an Exclusive Load transaction.
- If the LP holds the cache line in a Shared state, it is permitted, but not required, that it performs an Exclusive Load transaction.
- If the LP does not hold a copy of the cache line, it is recommended that the LP uses an Exclusive Load transaction to obtain the cache line. It is permitted to use ReadClean, ReadShared, ReadNotSharedDirty, or ReadPreferUnique without the Excl attribute asserted.

Snoopable Exclusive Load to Snoopable Exclusive Store

After the execution of an Exclusive Load, an LP will typically calculate a new value to store to the location before it attempts the Exclusive Store.

It is not required that an LP always completes an Exclusive sequence. For example, the value obtained by the Exclusive Load can indicate that a semaphore is held by another LP and that the value cannot be changed until the semaphore is released by the other LP. Therefore, a new Exclusive sequence can be started with no attempt to complete the current Exclusive sequence.

During the time between the Exclusive Load and the Exclusive Store, the LP exclusive monitor must monitor the location to determine whether another LP might have updated the location.

Snoopable Exclusive Store

An LP must not permit an Exclusive Store transaction to be in progress at the same time as any transaction that registers that it is performing an exclusive sequence. The LP must wait for all messages for any such transaction to be exchanged, or to receive a RetryAck response, before issuing an Exclusive Store transaction. The transactions that register that an LP is performing an exclusive sequence are:

- Exclusive Load transactions to any location.
- Exclusive Store transactions to any location.

When an LP executes an Exclusive Store the following behavior is required:

- If the LP exclusive monitor has been reset the Exclusive Store must fail and the LP must not issue an Exclusive Store transaction. The LP must restart the exclusive sequence.

———— **Note** ————

When the LP monitor has been reset, not issuing a transaction for an Exclusive Store that must eventually fail avoids unnecessary invalidation of other copies of the cache line.

- If the cache line is held in a Unique state and the LP exclusive monitor is set, then the Exclusive Store has passed and it can update the location without issuing a transaction.

- If the cache line is held in a Shared state and the LP exclusive monitor is set, the LP must issue an Exclusive Store transaction. A CleanUnique or MakeReadUnique transaction with the Excl attribute asserted must be used. The LP exclusive monitor must continue to operate and check that the cache line is not updated while the CleanUnique or MakeReadUnique transaction is in progress.

An Exclusive CleanUnique transaction response is handled in the following way.

The transaction will receive a Normal Okay or an Exclusive Okay response.

If the transaction receives an Exclusive Okay response, this indicates that the transaction has passed and has completed invalidating all other copies of the cache line. After an exclusive transaction completes with an Exclusive Okay response, the LP must again check the LP exclusive monitor:

- If the LP exclusive monitor is set, the Exclusive Store has passed and the update is performed.
- If the LP exclusive monitor is not set, it indicates that an update to the cache line has occurred between the point that the Exclusive Store transaction was issued and the point that it completed. The Exclusive Store must fail and the exclusive sequence must be restarted.
- If the LP has not been able to track the exclusive nature of the cache line, because the cache line has been evicted, then the Exclusive Store must fail and the exclusive sequence must be restarted.

If the Exclusive Store transaction receives a Normal Okay response, this indicates another LP has been permitted to progress a transaction associated with an Exclusive Store. The transaction associated with the Exclusive Store, from this LP, has failed and has not propagated to other Logical Processors in the system. When an Exclusive Store transaction completes with a Normal Okay response, the options are:

- The LP can fail the Exclusive Store and restart the exclusive sequence with or without checking the state of the cache line when the access completed.
- The LP can check the LP exclusive monitor, and if the LP exclusive monitor has been reset, the LP must fail the Exclusive Store and restart the exclusive sequence.
- The LP can check the LP exclusive monitor, and if the LP exclusive monitor is set, the LP can repeat the Exclusive Store transaction.

For handling of an Exclusive MakeReadUnique at the Home Node see [Home behavior on page 6-298](#).

Exclusive accesses to Non-snoopable locations

The following restrictions apply to Exclusive accesses to Non-snoopable locations:

- The address of an Exclusive access must be aligned to the total number of bytes in the transaction.
- The number of bytes to be transferred in an Exclusive access must be a legal data transfer size. This is 1 byte, 2 bytes, 4 bytes, 8 bytes, 16 bytes, 32 bytes, or 64 bytes.

Failure to observe these restrictions results in behavior that is UNPREDICTABLE.

For Exclusive read and Exclusive write transactions to be considered a pair, the following criteria must apply:

- The addresses of the Exclusive read and the Exclusive write must be identical.
- The value of the control signals, that is MemAttr and SnpAttr of the Exclusive read and the Exclusive write transaction, must be identical.
- The data size in the Exclusive read and the Exclusive write must be identical.
- The LPID value of the Exclusive read must match the LPID value of the Exclusive write transaction.

The minimum number of bytes to be monitored during an exclusive operation is defined by the transaction size. The System monitor can monitor a larger number of bytes, up to 64 bytes, which is the maximum size of an Exclusive access. However, this can result in a successful Exclusive access being indicated as failing because a neighboring byte was updated while the Exclusive access was in progress.

Multiple Exclusive transactions to Non-snoopable memory locations, either read or write, to the same or different addresses, from the same LP must not be outstanding at the same time.

If the Subordinate Node does not support Exclusive accesses, as indicated by an Exclusive Fail on the Exclusive ReadNoSnp, the write will update the location if the write is given an Exclusive Fail response.

If the Subordinate Node does support Exclusive accesses, as indicated by an Exclusive Pass on the Exclusive ReadNoSnp, the write will not update the location if the write is given an Exclusive Fail response.

Chapter 7

Cache Stashing

This chapter describes the cache stashing mechanism whereby data that is written from a Request Node can be installed in a peer cache. It contains the following sections:

- [Overview on page 7-304](#)
- [Write with Stash hint on page 7-306](#)
- [Independent Stash request on page 7-307](#)
- [Stash target identifiers on page 7-309](#)
- [Stash messages on page 7-310](#)

7.1 Overview

Cache stashing is a mechanism to install data within particular caches in a system. Cache stashing ensures that data is located close to its point of use, improving the system performance.

Cache stashing is permitted to Snoopable memory only.

This specification supports two main forms of cache stashing transaction:

WriteUniqueStash

Write with stash hint. This is used when the cache in which the data should be allocated is known at the point in time that the data is written. A write with stash hint can be a [Full] or [Ptl] cache line write, and this will affect the Snoop transactions that are used. See [Write with Stash hint on page 7-306](#).

StashOnce

Independent stash request. This is used when the request to stash data into a particular cache is separated from the writing of the data. An independent Stash transaction can indicate if the cache line should be held in a Unique or Shared state by using a StashOnceUnique or StashOnceSepUnique, or a StashOnceShared or StashOnceSepShared transaction respectively, which corresponds to whether the next expected use of the cache line is for storing or for reading. See [Independent Stash request on page 7-307](#).

Both forms of cache stashing can target installation of data at different cache levels. The Stash target cache can be a peer cache, specified by using the peer cache target NodeID, or an LP cache within the peer node, if the peer node has multiple logical processors. The LP is identified by the LPID in the target cache field. See [Stash target identifiers on page 7-309](#).

The Cache stashing requests can also target the cache below the peer cache in the cache hierarchy, which can be an interconnect cache or a system cache. This is done by not specifying the peer cache NodeID. See [Stash target not specified on page 7-309](#).

In all cases of cache stashing, the Stashing is only a performance hint and it is permitted for the Stash request receiver to not perform the stashing behavior.

7.1.1 Snoop requests and Data Pull

The following Snoop requests are used to notify a peer cache that it is the target of a Stash request:

- SnpUniqueStash
- SnpMakeInvalidStash
- SnpStashUnique
- SnpStashShared

[Table 7-1](#) shows the Snoop requests associated with each of the Stash requests.

Table 7-1 Stash request and the corresponding Snoop request

Stash request	Snoop request
WriteUniquePtlStash	SnpUniqueStash
WriteUniqueFullStash	SnpMakeInvalidStash
StashOnceUnique StashOnceSepUnique	SnpStashUnique
StashOnceShared StashOnceSepShared	SnpStashShared

A Snoopee that receives a Stash Snoop request does one of the following:

- Provides a Snoop response that also acts as a Read request for the associated cache line. Including a Read request with Snoop response is referred to as a Data Pull. [Table 7-2](#) shows the type of Read request that is implied by a Data Pull in the response to each Stash Snoop request.

Table 7-2 Snoop response with Data Pull and implied Read request

Snoop request	Implied Read request
SnpUniqueStash	ReadUnique
SnpMakeInvalidStash	ReadUnique
SnpStashUnique	ReadUnique
SnpStashShared	ReadNotSharedDirty

- Provides a Snoop response without a Data Pull response so ignoring the cache stash hint.

The value of the DataPull field in the SnpResp and SnpRespData responses indicates if DataPull is requested. See [Data Pull, DataPull on page 13-441](#) for legal values for DataPull.

The use of DataPull to complete a Snoop request with Stash is optional.

If the Snoopee is not able to support the DataPull transaction flow, it is permitted to ignore the stash operation.

7.2 Write with Stash hint

The rules for sending and processing a WriteUniqueFullStash and WriteUniquePtlStash request at the Stash requester, the Home, and the Stash target node are as follows:

Requester responsibilities:

- Sends a WriteUniqueFullStash or WriteUniquePtlStash request depending on whether a full cache line or a partial cache line is to be written.
- The request is expected to include a Stash target.

Home responsibilities:

- Permitted to send a RetryAck response to a WriteUniqueStash request and follow the Retry transaction flow.
- Sends SnpUniqueStash to the identified Stash target.
- Sends SnpUnique to all other Requesters that share the cache line.
- Permitted to send SnpMakeInvalidStash and SnpMakeInvalid instead of SnpUniqueStash and SnpUnique respectively for WriteUniqueFullStash.
- Send Comp to the Requester after the coherency action is completed.
- Permitted to ignore the stash hint in the Write request and process the request as a regular WriteUnique.
- Handles a request without a Stash target in the manner described in [Stash target not specified on page 7-309](#).
- Permitted to use DMT to get data from SN-F to the Stash target in response to a Data Pull request, when the data is neither available at Home nor obtained from any caches.
- Permitted to use separate Non-data and Data-only response to the Stash target in response to a Data Pull request.

The Stash target responsibilities:

- The responses that include Data Pull are:
 - SnpResp_I_Read
 - SnpRespData_I_Read
 - SnpRespData_I_PD_Read
 - SnpRespDataPtl_I_PD_Read
- Must not request Data Pull if:
 - Snoop has an address hazard with an outstanding request.
 - The Stash target has an outstanding request to the same address that has received a DBIDRespOrd but has not completed.
- When requesting Data Pull:
 - The Stash target must guarantee the Read data is accepted without any structural or protocol dependencies that might result in deadlock.
 - The Read request is treated by Home as ReadUnique.
 - The Stash target must populate the DBID field in the response with the TxnID that is to be used by Home for the Read transaction. If the Snoop response with DataPull includes data, the DBID field value in all data packets must be the same.
- Permitted to ignore the Stash hint and handle the snoop as SnpUnique.

7.3 Independent Stash request

The second mechanism for implementing cache stashing is to permit the Stash request to be sent separated in time from the writing of Stash data. Examples of when such a mechanism is useful are:

- When the data that is being written is not required by the target immediately. This delayed Stash avoids polluting the cache with data that is not used immediately.
- When the data is already in the system and the data has to be prefetched into caches.
- When the process using the data being written is not scheduled when the data is written, and therefore the precise target of the Stash data is not known until later.

In these cases, a Requester can use StashOnce or StashOnceSep requests to request Home or a peer node to fetch a cache line.

The rules for sending and processing an independent Stash request at the Stash requester, Home, and the Stash target are as follows:

Requester Node responsibilities:

- Sends StashOnceUnique or StashOnceSepUnique to Home if the stashed cache line is to be modified.
- Sends StashOnceShared or StashOnceSepShared to Home if the stashed cache line is not to be modified.
- Sends StashOnceSep only if the Requester is capable of handling the StashDone response.
- The StashOnce and StashOnceSep requests provide a Stash target when the data is to be stashed in a peer cache.
- The StashOnce and StashOnceSep requests do not provide a Stash target when the data is to be allocated in the next level cache.
- The Requester, upon receiving the Comp response, is permitted to release some request resources, while keeping track of the number of outstanding StashDone responses. This count of the number of outstanding StashDone responses can be done per Stash group, using the Requester defined Stash Group ID, specified by the StashGroupID field value.

Home Node responsibilities:

- Permitted to send a RetryAck response to a Stash request and follow the Retry transaction flow.
- Send a SnpStashUnique to the target RN-F for StashOnceUnique and StashOnceSepUnique.
- Send a SnpStashShared to the target RN-F for StashOnceShared and StashOnceSepShared.
- Permitted to not send a Snoop request in response to a Stash request.
- Must send a Comp response, even if it abandons the Stash request.
- For the StashOnce, the Home must send a Comp only after establishing processing order for the received request that is guaranteeing that any request to the same address received later from any Requester is ordered behind this request. The Comp response must come from the PoC.
- For the StashOnceSep request, the Home must send a Comp only after establishing the guarantee that it will not send a RetryAck response. The StashDone response must only be sent after establishing the guarantee that the request is ordered at the Home.
- Fetches the addressed cache line from memory into the shared system cache when a Stash request without a Stash target is received.
- Permitted to send Comp after receiving the Stash request, and before sending any SnpStash* or receiving the Snoop response.
- Send Comp with a Non-Invalid state, if the cache line is cached in the cache at the next level.

Send Comp_I if the cache line is not cached, or it is not known if the cache line is cached, in the cache at the next level.

- Send a Comp_I response if either the cache look up at Home is a miss or Home did not look up the cache before responding.
- Permitted to use DMT to get data from SN-F to the Stash target in response to a Data Pull request.
- Permitted to use separate Non-data and Data-only response to the Stash target in response to a Data Pull request.

Stash target responsibilities:

- The snoop must not change the state of the cache line at the Stash target.
- The snoop is treated as a hint at the Stash target to obtain a copy of the cache line.
- Must not request DataPull if:
 - Snoop has an address hazard with an outstanding request.
 - Response is sent before performing a local cache lookup.
 - The snoop is SnpStashShared and the cache has a copy of the cache line.
 - The Stash target has an outstanding request to the same address that has received a DBIDRespOrd but not yet completed.
- When requesting DataPull:
 - The Stash target must guarantee the Read data is accepted without any structural or protocol dependencies that might result in deadlock.
 - The DataPull request is treated by Home as ReadNotSharedDirty for SnpOnceShared.
 - The DataPull request is treated by Home as ReadUnique for SnpOnceUnique.
 - The Home must treat the Stash request and the DataPull request atomically as a single request. That is, the Home must not order any other request to the same address between the Stash request and the corresponding DataPull request.
 - The Stash target must populate the DBID field in the response with the TxnID that is to be used by Home for the Read transaction.
- A DataPull request can be sent, but is not required to be sent, when the snoop is SnpStashUnique and a shared copy is present.
- The Stash target is permitted, but not required, to wait until it completes the local cache lookup before sending the Snoop response.
- The cache state in the Snoop response is not required to be precise:
 - An imprecise response must be SnpResp_I.
 - Any state other than I in the response must be precise.

Note

- For StashOnce*, care is needed to avoid any action that could result in the deallocation of the cache line from the cache where it is expected to be used.
- A StashOnce*Unique transaction can cause the invalidation of a copy of the cache line and care must be taken to ensure such transactions do not interfere with Exclusive access sequences.

The requirements regarding the sending of Stash type snoops from a Home, and the permitted responses by the target, are the same as the request/response rules for StashOnceSep transactions. See [Stash transactions on page 2-76](#).

7.4 Stash target identifiers

For all Stash requests, both options of specified and non-specified Stash target are supported.

7.4.1 Stash target specified

If the Stash target is available in the Stash request then Home sends the snoop with a stash hint to the specified target. The specified target can be a Request Node or an LP within a Request Node.

7.4.2 Stash target not specified

The Home Node that receives a WriteUniquePtlStash or WriteUniqueFullStash request without a Stash target does the following:

- If the cache line is cached in a Unique state at a Request Node, the Home can treat that Request Node as the Stash target.
- If the cache line is not cached in a Unique state, the Home must only send SnpUnique as required, and must not send SnpUniqueStash to any Request Node.
- For WriteUniquePtlStash, if the cache line is not in any cache, it is recommended that the Home prefetches and allocates the cache line in the system cache. It is permitted, but not recommended, to perform a partial write to main memory.
- For WriteUniqueFullStash, if the cache line is not in any cache then Home is permitted to allocate the cache line in the shared system cache.

The Home Node that receives a StashOnce or StashOnceSep request without a Stash target does the following:

- If the cache line is not cached in any peer cache, it is recommended that the cache line is allocated in the shared system cache.
- If the cache line is cached in a peer cache, it is IMPLEMENTATION DEFINED if a snoop is sent to transfer a copy of the cache line and allocate it in the shared system cache. For StashOnceUnique and StashOnceSepUnique, it is also IMPLEMENTATION DEFINED if all cached copies are invalidated before allocating the cache line in the shared system cache.

7.5 Stash messages

Stash messages are classified as:

- Write requests:
 - WriteUniqueFullStash
 - WriteUniquePtlStashSee [Write transactions on page 4-187](#).
- Dataless requests:
 - StashOnceUnique
 - StashOnceSepUnique
 - StashOnceShared
 - StashOnceSepSharedSee [Dataless transactions on page 4-180](#).
- Snoop requests:
 - SnpUniqueStash
 - SnpMakeInvalidStash
 - SnpStashUnique
 - SnpStashSharedSee [Snoop request types on page 4-201](#).
- Stash responses:
 - Comp
 - StashDone
 - CompStashDoneSee [Stash transactions on page 2-76](#).

7.5.1 Supporting REQ packet fields

The fields defined in the REQ packet to support Stash requests are:

- StashNID, StashLPID
- StashNIDValid, StashLPIDValid

[Table 7-3](#) shows the valid StashNIDValid and StashLPIDValid encodings.

Table 7-3 Valid StashNIDValid and StashLPIDValid encodings

StashNIDValid	StashLPIDValid	Comments
0	0	Stash target is not specified
0	1	Reserved
1	0	Only a target RN is specified
1	1	Both target RN and LPID are specified

See [Protocol flit fields on page 13-424](#).

7.5.2 Supporting SNP packet fields

The fields defined in the SNP packet to support Stash requests are:

- StashLPID
- StashLPIDValid

See [Protocol flit fields on page 13-424](#).

7.5.3 Supporting RSP packet field

The field defined in the RSP packet to support Stash requests is DataPull.

See [Protocol flit fields on page 13-424](#).

7.5.4 Supporting DAT packet fields

The field defined in the DAT packet to support Stash requests is DataPull.

See [Protocol flit fields on page 13-424](#).

Chapter 8

DVM Operations

This chapter describes *Distributed Virtual Memory* (DVM) operations that the protocol uses to manage virtual memory. It contains the following sections:

- [*DVM transaction flow* on page 8-314](#)
- [*DVM Operation types* on page 8-323](#)
- [*DVM Operations* on page 8-330](#)

8.1 DVM transaction flow

All DVM transactions have similar requirements and are mapped to a single flow. The following sections show the Non-sync and Sync DVM transaction requirements:

- [Non-sync type DVM transaction flow](#)
- [Sync type DVM transaction flow on page 8-315](#)
- [Flow control on page 8-317](#)
- [DVMOp field value restrictions on page 8-318](#)
- [Field value requirements on page 8-322](#)

8.1.1 Non-sync type DVM transaction flow

Figure 8-1 shows the steps in a Non-sync type DVM transaction.

Figure 8-1 Non-sync type DVM transaction flow

The required steps that [Figure 8-1 on page 8-314](#) shows are:

1. RN-F0 sends a DVMOp(Non-sync) to the Miscellaneous Node using the appropriate write semantics for the DVMOp type.
2. The Miscellaneous Node accepts the DVMOp(Non-sync) request and provides a DBIDResp response.
3. The RN-F0 sends an 8-byte data packet on the data channel.
4. The MN broadcasts the SnpDVMOp snoop request to all the RN-F and RN-D nodes in the system. The SnpDVMOp is sent on the Snoop channel, and requires two Snoop requests. The two parts of the SnpDVMOp are labeled by the suffix _P1 and _P2.

Note

- Both parts of the message must carry the same *Transaction ID* (TxnID).
 - The Request Node must have resources available to accept the SnpDVMOp. See [Flow control on page 8-317](#).
-

5. After completing the required actions, each recipient of the SnpDVMOp sends a single SnpResp response to the Miscellaneous Node.

Note

Sending of a SnpResp implies that the target Request Node has forwarded the SnpDVMOp to the required Request Node structures and has freed up the resources needed to accept another DVM operation. It does not imply that the requested DVM operation has completed. See [Sync type DVM transaction flow](#).

6. After receiving all the SnpResp responses, the Miscellaneous Node sends a Comp response to the requesting node.

DVM early Comp for Non-sync DVMOps

The Miscellaneous Node in the interconnect is permitted to send Comp for a Non-sync DVMOp without waiting to complete the required snooping of Request Nodes. Such a Miscellaneous Node must take the responsibility of ordering this Non-sync DVMOp against any Sync DVMOp received later from the same source. If a Miscellaneous Node cannot provide such an ordering guarantee, then it must wait for the snooping to be completed before sending a Comp response for a Non-sync DVMOp.

A Miscellaneous Node that is enabled to send early Comp for a Non-sync DVMOp is permitted to opportunistically combine Comp and DBIDResp responses into a single CompDBIDResp response.

Note

- Sending of a Comp response early for Non-sync DVMOp reduces round-trip latency for DVMOp completion. This enables a greater number of DVMOp transactions to be pipelined from a single source.
 - Such an early completion also enables a Sync DVMOp, which is waiting for completions of all related DVMOp transactions sent earlier from the same Request Node.
-

The Miscellaneous Node must still wait for the Snoop response for a Sync DVMOp to be received before sending a Comp to the Requester for that Sync DVMOp.

8.1.2 Sync type DVM transaction flow

[Figure 8-2 on page 8-316](#) shows the flow in a Sync DVM transaction.

Figure 8-2 Sync DVM transaction flow

The required steps that [Figure 8-2 on page 8-316](#) shows are:

1. RN-F0 sends a DVMOp(Sync) to the Miscellaneous Node.

———— Note ————

All previous DVMOp requests whose completion needs to be guaranteed by the DVMOp(Sync) must have received a Comp response before the Request Node can send a DVMOp(Sync).

2. The Miscellaneous Node accepts the DVMOp(Sync) request and sends a DBIDResp response to the Requester.
3. The RN-F0 sends a data packet on the data channel with a data size of 8 bytes.
4. The Miscellaneous Node sends the SnpDVMOp to RN-F1. The SnpDVMOp is sent on the Snoop channel, and requires two Snoop requests. The two parts of a SnpDVMOp are labeled by the suffix _P1 and _P2.
5. After completing the DVM Sync operation, RN-F1 sends a SnpResp response to the Miscellaneous Node.

———— Note ————

Sending of a SnpResp implies that all DVM-related operations have completed at the Request Node structures and the target Request Node has freed up the resources needed to accept another SnpDVMOp.

6. After receiving the SnpResp, the Miscellaneous Node sends a Comp response to RN-F0.

8.1.3 Flow control

DVMOp request flow control:

- A DVMOp can receive a RetryAck response from a Miscellaneous Node.
- A DVMOp that receives a RetryAck response must wait for a PCrdGrant response from the Miscellaneous Node that has the appropriate PCrdType.
- All previous DVMOp requests whose completion needs to be guaranteed by the DVMOp(Sync) must have received a Comp response before the Request Node can send the DVMOp(Sync).
- The interconnect must guarantee forward progress on DVMOp(Non-Sync), which requires that there should be at least one tracker entry in the Miscellaneous Node reserved for DVMOp(Non-Sync).
- It is permitted to overlap a DVMOp(Non-sync) and a DVMOp(Sync), from the same Request Node, if the DVMOp(Sync) is not required to guarantee completion of the DVMOp(Non-sync).

SnpDVMOp flow control:

- Each SnpDVMOp transaction requires two SnpDVMOp request packets.
- Both SnpDVMOp request packets corresponding to a single transaction must use the same TxnID.
- The two SnpDVMOp request packets corresponding to a single transaction can be sent or received in any order.
- Multiple SnpDVMOp(Non-sync) transactions can be outstanding from a Miscellaneous Node.
- Only one SnpDVMOp(Sync) transaction can be outstanding from a Miscellaneous Node to a Request Node.
- To prevent deadlocks, due to the two part SnpDVMOp requests that use the Snoop channel, a SnpDVMOp transaction must only be sent when the receiving Request Node has pre-allocated resources to accept both parts of the SnpDVMOp transaction.
- A Sync DVM operation at a Request Node that has issued a StashOnceSep request must wait until all outstanding StashDone responses are received for StashOnceSep requests that use invalidated page entries.

- A Request Node must provide a response to a SnpDVMOp transaction only after it has received both SnpDVMOp request packets corresponding to that transaction.
- A Request Node must provide a response to a SnpDVMOp only when it can accept a further SnpDVMOp from a Miscellaneous Node.
- When responding to a SnpDVMOp(Sync), a Request Node can depend on the forward progress of any transaction, except for the completion of an outstanding DVMOp(Sync) request.
- Each RN-F and RN-D in the system specifies the number of SnpDVMOp transactions it can accept concurrently.
- Each RN-F and RN-D in the system must be able to accept at least one SnpDVMOp(Non-Sync) transaction in addition to a SnpDVMOp(Sync) transaction.
- The minimum number of SnpDVMOp transactions that must be accepted concurrently is two. This is the default number for Request Nodes that do not specify a number.

8.1.4 DVMOp field value restrictions

Field value restrictions during a DVMOp transaction are shown:

- Request messages in [Table 8-1](#)
- Data messages in [Table 8-2 on page 8-319](#)
- Snoop messages in [Table 8-3 on page 8-320](#)
- Response messages:
 - DBIDResp, Comp, and SnpResp in [Table 8-4 on page 8-322](#)

[Table 8-1](#) shows the Request message field value restrictions for a DVMOp transaction.

Table 8-1 Request message field value restrictions for DVMOp

Field Name	Restriction
QoS	None. Can take any value.
TgtID	Expected to be node ID of Miscellaneous Node. Can be remapped to correct TgtID by the interconnect.
SrcID	Source ID of the Requester that initiated the DVM message.
TxnID	An ID generated by the Requester. Must follow the same rules as any other transaction.
ReturnNID StashNID SLCRepHint	Must be all zeros.
StashNIDValid Endian Deep	Must be zero.
ReturnTxnID StashLPIDValid StashLPID	Must be all zeros.
Opcode	Must be DVMOp.
Size	Must be 8-byte.

Table 8-1 Request message field value restrictions for DVMOp (continued)

Field Name	Restriction
Addr	Req_Addr_Width. See DVM Operations on page 8-330
NS	Must be zero.
LikelyShared	Must be zero.
AllowRetry	Can take any value, because a DVMOp can be given a Retry.
Order	Must be all zeros
PCrdType	Must be all zeros if AllowRetry is asserted, otherwise the Credit type value.
MemAttr	Must be all zeros.
SnprAttr	None. Can take any value. See DVM domain on page 8-329 .
LPID	None. Can take any value.
Excl SnoopMe	Must be zero.
ExpCompAck	Must be zero.
TagOp	Must be zero.
TraceTag	None.
MPAM	Must be all zeros.
RSVDC	None. Can take any value.

[Table 8-2](#) shows the Data message field value restrictions for a DVMOp transaction.

Table 8-2 Data message field value restrictions for DVMOp

Field Name	Restriction
QoS	None. Can take any value.
TgtID	Must be the same as SrcID returned in the DBIDResp response.
SrcID	Must be ID of the original Requester.
TxnID	Must be the same as DBID of the DBIDResp response.
HomeNID	Must be all zeros.
Opcode	Must be NonCopyBackWriteData.
RespErr	Must be 0b00 or 0b10.
Resp	Must be all zeros.

Table 8-2 Data message field value restrictions for DVMOp (continued)

Field Name	Restriction
FwdState DataPull DataSource	Must be all zeros.
CBusy	Must be all zeros.
DBID	None. Can take any value.
CCID	Must be all zeros.
DataID	Must be all zeros.
TagOp	Must be all zeros.
Tag	Must be zero.
TU	Must be zero.
TraceTag	None.
RSVDC	None.
BE	Only BE[7:0] must be asserted.
Data	Unused bits must be zero for Data[63:0] and Data[n:64] = Can take any value.
DataCheck	Must be the appropriate value for the Data field.
Poison	None. Can take any value.

[Table 8-3](#) shows the Snoop message field (SnpDVMOp) value restrictions during a DVMOp transaction.

Table 8-3 Snoop message field value restrictions for DVMOp

Field Name	Restriction
QoS	None. Can take any value.
SrcID	Must be node ID of MN.
TxnID	An ID generated by MN.
FwdNID	None. Used as Range and Num[4:0] fields. See Table 8-7 on page 8-328
VMIDExt	Must be used for VMID[15:8] in Part 1 of the SnpDVMOp request. None, can take any value in Part 2 of the SnpDVMOp request.
Opcode	Must be SnpDVMOp.
Addr	(Req_Addr_Width - 3). See DVM Operations on page 8-330 .
NS	Must be zero.
DoNotGoToSD	Must be zero.

Table 8-3 Snoop message field value restrictions for DVMOp (continued)

Field Name	Restriction
RetToSrc	Must be zero.
TraceTag	None.
MPAM	Must be all zeros.

Table 8-4 shows the Response DBIDResp, SnpResp, and Comp and CompDBIDResp message field value restrictions during a DVMOp transaction.

Table 8-4 Restrictions for response message field values during DVMOp

Response messages			
Field	DBIDResp	Comp and CompDBIDResp	SnpResp
QoS	None. Can take any value	None. Can take any value	None. Can take any value
TgtID	Must be ID of the original Requester	Must be ID of the original Requester	Must be the ID of the MN that is handling DVMOps
SrcID	Must be ID of the MN that is handling DVMOps	Must be ID of the MN that is handling DVMOps	Must be the node ID that is responding to snoops
TxnID	Must match TxnID of the original request	Must match TxnID of the original request	Must match the TxnID of the SnpDVMOp snoop request
Opcode	Must be DBIDResp	Must be Comp or CompDBIDResp	Must be SnpResp
RespErr	Must be all zeros	Must be 0b00, 0b10, or 0b11	Must be all zeros
Resp	Must be all zeros	Must be all zeros	Must be all zeros
FwdState DataPull	Must be all zeros	Must be all zeros	Must be all zeros
CBusy	Expected to be populated by the Completer	Expected to be populated by the Completer	Expected to be populated by the Completer
DBID TagGroupID StashGroupID PGroupID	Generated by the MN that is handling DVMOps	Generated by the MN that is handling DVMOps	None. Can take any value
PCrdType	Must be all zeros	Must be all zeros	Must be all zeros
TagOp	Must be all zeros	Must be all zeros	Must be all zeros
TraceTag	None	None	None

8.1.5 Field value requirements

Both SnpDVMOp request packets, corresponding to a single DVMOp, must have the same value in the following fields:

- TxnID
- Opcode
- SrcID
- TgtID

8.2 DVM Operation types

The following DVM Operations are supported:

- TLB Invalidate.
- Branch Predictor Invalidate.
- Instruction Cache Invalidate:
 - Physical address invalidate.
 - Virtual address invalidate.
- Synchronization.

8.2.1 DVMOp payload

The payload of a DVM operation from the Request Node to the Miscellaneous Node is distributed within:

- The address field in the DVM request from the Request Node.
- The lower 8 bytes of write data in the NonCopyBackWrData packet.

The payload of a DVM operation from the Miscellaneous Node to the Request Node is distributed over two SnpDVMOp request packets using the address fields.

The various fields in the payload and their encodings are shown in [Table 8-5](#).

Table 8-5 DVMOp fields and encodings

Field	Bits	Function
VA Valid	1	0b1 indicates that the specified address is valid.
VI Valid	2	<i>Virtual Index</i> (VI) Valid. Used as part of PICI operations. 0b00 VI not valid. 0b01 Reserved. 0b10 Reserved. 0b11 VI is valid.
VMID Valid	1	0b1 indicates that the <i>Virtual Machine Identifier</i> (VMID) is valid.
ASID Valid	1	0b1 indicates that the <i>Address Space Identifier</i> (ASID) is valid.
Security	2	Indicates that the transaction applies to: 0b00 Secure and Non-secure 0b01 Non-secure address from a Secure context 0b10 Secure and Non-secure if DVMOp type is PICI and invalidation is all. Secure in all other cases. <hr/> Note This update applies retrospectively to all prior issues of this specification. <hr/> 0b11 Non-secure
Exception Level	2	Indicates that the transaction applies to: 0b00 Hypervisor and all Guest OS 0b01 EL3 ^a 0b10 Guest OS 0b11 Hypervisor

Table 8-5 DVMOp fields and encodings (continued)

Field	Bits	Function
DVMOp type	3	Indicates the DVM operation type as: 0b000 TLB Invalidate (TLBI) 0b001 Branch Predictor Invalidate (BPI) 0b010 Physical Instruction Cache Invalidate (PICI) 0b011 Virtual Instruction Cache Invalidate (VICI) 0b100 Synchronization 0b101-0b111 Reserved
VMID	8	Virtual Machine ID VMID[7:0]
ASID	16	Address Space ID
Staged Invalidation	2	Indicates Stage 2 or Stage 1 invalidation: 0b00 • DVMv7: Any transaction. • DVMv8: Both Stage 1 and Stage 2 invalidation. 0b01 Stage 1 invalidation only. 0b10 Stage 2 invalidation only. 0b11 Reserved.
Leaf Entry Invalidation	1	0b1 indicates that only leaf level translation invalidation is required.
Range ^b	1	Range can take any value. When: Range = 1 The transaction is a range-based TLBI operation. Range = 0 The transaction is a non-range based TLBI operation. Range is inapplicable and must be zero for non-TLBI DVM transactions.
Num ^b	5	Used as a constant multiplication factor in the range calculation. All binary values are valid.
Scale ^b	2	Used as a constant in address range exponent calculation. All binary values are valid.
TTL ^b	2	Hint of <i>Translation Table Level</i> (TTL) which includes the addresses to be invalidated: 0b00 The leaf level for the entries to invalidate can be any level of the walk. 0b01 The leaf level for the entries to invalidate is level 1. 0b10 The leaf level for the entries to invalidate is level 2. 0b11 The leaf level for the entries to invalidate is level 3.
TG ^b	2	<i>Translation Granule</i> (TG) size takes the following values: 0b00 When Range = 0: No level hint is provided. TTL is Reserved. When Range = 1: Reserved. 0b01 4K 0b10 16K 0b11 64K
BaseAddr or VA or PA	37 49-53 44-52	Range base address Virtual address Physical address
VI	16	Virtual index
VMIDExt	8	Virtual Machine ID VMID[15:8]

a. DVMv8 only.

b. Inapplicable and must be set to zero in non-TLBI DVM Operations. See [Range-based TLBI payload on page 8-326](#) and [Level Hint in TLBI Operations on page 8-328](#) for details of how these fields are used in TLBI operations.

8.2.2 DVMOp and SnpDVMOp packet

Table 8-6 shows the distribution of the payload in the DVMOp request from the Request Node, using 8-byte write semantics, and the distribution of the payload in the SnpDVMOp requests from the Miscellaneous Node.

In the DVMOp, the combination of the address field in the request and the 8-byte write data transports the complete payload. REQ.Addr[3] is not used in the request and must be set to zero.

In the two SnpDVMOp requests the combination of the two address fields transports the complete payload. SNP.Addr[0] is used in a SnpDVMOp request to indicate which part of the payload is being transported.

The valid combinations of *Maximum PA* (MPA) and *Maximum VA* (MVA) address bits are:

- MPA = 44 : MVA = 49
- MPA = 45 : MVA = 51
- MPA = 46 to 52 : MVA = 53

See [Range-based TLBI payload on page 8-326](#) and [Level Hint in TLBI Operations on page 8-328](#).

Table 8-6 DVMOp and SnpDVMOp request payloads

DVMOp Request				SnpDVMOp Request			
X in REQ.Addr[x] DAT.Data[x]	Num bits	Request	Data	SNP.Addr[x]	Num bits	Part 1	Part 2

48:46	3	-	VA[50:48] PA[50:48]	45:43	3	-	PA[50:48]
49	1	-	VA[51] PA[51]	46	1	-	PA[51]
50	1	-	VA[52]	47	1	-	-
55:51	5	-	-	48	1	-	-
63:56	8	-	VMID[15:8] ^d				

- For part two of a SnpDVMOp request, Num[4:0] from the corresponding DVMOp request is carried on the FwdNID field of the Snoop flit alongside the Addr field. See [Table 8-7 on page 8-328](#).
- When used as Virtual Index (VI), REQ.Addr[37:30], DAT.Data[37:30], and SNP.Addr[34:27] can take any value.
- For part one of a SnpDVMOp request, Range from the corresponding DVMOp request is carried on the FwdNID field of the Snoop flit alongside the Addr field. See [Table 8-7 on page 8-328](#).
- For part one of a SnpDVMOp request, VMID[15:8] from the corresponding DVMOp request is carried on the VMIDExt field of the Snoop flit alongside the Addr field. See [Table 13-8 on page 13-421](#).

Range-based TLBI payload

Range-based TLBI operations include range-specific payload in addition to the payload fields in non-range-based TLBI operation. These additional range-based payload fields are applicable in both TLBI operation by VA and IPA.

———— **Note** ————

Prior to CHI Issue E, range-based TLBI operations are not defined.

The range-based fields are Range, BaseAddr, TG, TTL, Scale, and Num. These definitions of the fields and how they are used to compute the address range to invalidate is given below.

Range payload packing

Address range to invalidate is calculated using the following formula:

$$\text{Base Addr} \leq \text{Addr to invalidate} < \text{Base Addr} + ((\text{Num}+1) * 2^{(5*\text{Scale}+1)} * \text{TG})$$

Where:

BaseAddr	Shifted Base address of the range - 37 bits. The base address in the message is shifted based on the Transaction granule. The lowest address bit carried in the message is Address[12], Address[14], and Address[16] for Transaction Granule size of 4K, 16K, and 64K, respectively.								
TG	Translation Granule Size - 2 bits, takes the following values: <table> <tr> <td>0b00</td><td>Reserved</td></tr> <tr> <td>0b01</td><td>4K</td></tr> <tr> <td>0b10</td><td>16K</td></tr> <tr> <td>0b11</td><td>64K</td></tr> </table>	0b00	Reserved	0b01	4K	0b10	16K	0b11	64K
0b00	Reserved								
0b01	4K								
0b10	16K								
0b11	64K								
TTL	Translation Table Level - 2-bits.								
Scale	2 bits, constant used in the address range exponent calculation. All binary values are valid.								
Num	5 bits, constant used as multiplication factor in the range calculation. All binary values are valid.								

The total number of bits in the Address range calculation is 48.

The range parameters are placed in the request packets as shown in [Table 8-6 on page 8-325](#). The Range and Num values are carried on the FwdNID field in the Snoop flit alongside the Addr field for the corresponding Snoop transaction. Unused bits of FwdNID in SnpDVMOp must be set to zero.

Base address of the range operation is placed in VA[MaxVA:12], with significant address bits adjusted TG value in the following manner.

TG = 4K	VA[MaxVA:12].
TG = 16K	VA[MaxVA:14]; VA[13:12] must be set to zero.
TG = 64K	VA[MaxVA:16]; VA[15:12] must be set to zero.

Table 8-7 shows the placement of the Range and Num values in the SnpDVMOp payload.

Table 8-7 Num value placement in SnpDVMOp payload

FwdNID	SnpDVMOp request	
	Part 1	Part 2
0	Range	Num[0]
1	0	Num[1]
2	0	Num[2]
3	0	Num[3]
4	0	Num[4]
5	0	0
6	0	0

Level Hint in TLBI Operations

Non-range based TLBI operations by VA or IPA are permitted to use TG and TTL. These operations use TG and TTL as an indication of the level of the page table walk that holds the leaf entry for the address that is being invalidated. For such operations:

- Range field must be set to zero.
- Num and Scale fields are inapplicable and must be set to zero.
- When TG[1:0] = 00, TTL information is not provided.

TG and TTL fields are inapplicable and must be set to zero in non-range based TLBI operations which are not by VA or IPA.

Range, Num, Scale, TG, and TTL fields are inapplicable and must be set to zero in all non-TLBI DVM operations.

8.2.3 DVM domain

The SnpAttr bit in a DVM request is used to differentiate between Inner and Outer domain. [Table 8-8](#) shows the SnpAttr value encoding in DVM transactions.

Table 8-8 SnpAttr value encoding in DVM transactions

SnpAttr	Domain value
0	Inner domain
1	Outer domain

Two additional optional interface broadcast pins **BROADCASTTLBIINNER** (BTI) and **BROADCASTTLBIOUTER** (BTO) are defined that determine broadcasting of TLBI operations in the interconnect. See [Optional interface broadcast signals on page 16-482](#).

8.3 DVM Operations

This section describes the supported DVM Operations:

- [TLB Invalidate](#)
- [Branch Predictor Invalidate](#) on page 8-336
- [Instruction cache invalidations](#) on page 8-337
- [Synchronization](#) on page 8-339

8.3.1 TLB Invalidate

This section shows the supported TLB Invalidate operations.

- [TLB Invalidate, All Guest OS, Secure operations](#)
- [TLB Invalidate, All Guest OS, Non-secure IPA, Secure operations](#) on page 8-331.
- [TLB Invalidate, All Guest OS, Non-secure operations](#) on page 8-332
- [TLB Invalidate, Hypervisor, Secure operations](#) on page 8-332
- [TLB Invalidate, Hypervisor, Non-secure operations](#) on page 8-334
- [TLB Invalidate EL3, Secure operations](#) on page 8-334

TLB Invalidate, All Guest OS, Secure operations

[Table 8-9](#) shows the fixed value fields for TLB Invalidate, All Guest OS, Secure operations.

Table 8-9 TLB Invalidate, All Guest OS, Secure operations fixed values

Field	Value	Status
DVMOp Type	0b000	TLBI
Exception Level	0b10	All Guest OS
Security	0b10	Secure

[Table 8-10](#) shows the TLB Invalidate values for All Guest OS, Secure operations. In [Table 8-10](#), the VA field holds the IPA or PA as required.

Table 8-10 TLB Invalidate, All Guest OS, Secure operations

Addr					Operation
ASID valid	VMID valid	Leaf Entry Invalidation	Staged Invalidation	VA valid	
0b0	0b0	0b0	0b00 ^a	0b0	Secure TLB Invalidate all

8.3.2 Branch Predictor Invalidate

This section shows the Branch Predictor Invalidate operations.

Table 8-21 shows the fixed value fields in the Branch Predictor Invalidate operation.

Table 8-21 Branch Predictor Invalidate operation fixed values

Field	Value	Status
Part Num	-	See Table 8-6 on page 8-325
VMID Valid	0b0	VMID field not valid
ASID Valid	0b0	ASID field not valid
Security	0b00	Applies to both secure and Non-secure
Exception Level	0b00	Applies to all Guest OS and Hypervisor
VMID VMIDExt	0xxx	VMID not specified
ASID	0xxxxx	ASID not specified
Staged Invalidation	0b00	Reserved, set to Zero
Leaf Entry Invalidation	0b0	Reserved, set to Zero

Note

The use of Branch Predictor Invalidate with a 16-bit ASID is not supported.

Table 8-22 shows the operations supported by Branch Predictor Invalidate.

Table 8-22 Branch Predictor Invalidate operations

Addr		Operation
DVMOp type	VA valid	
0b001	0b0	Branch Predictor Invalidate all
	0b1	Branch Predictor Invalidate by VA

8.3.3 Instruction cache invalidations

Instruction caches can use either a PA or a VA to tag the data they contain. A system might contain a mixture of both forms of cache.

The DVM protocol includes instruction cache invalidation operations that use physical addresses and operations that use virtual addresses. A component that receives DVM messages must support both forms of message, independent of the style of instruction cache implemented. It might be necessary to over-invalidate in the case where a message is received in a format that is not native to the cache type.

Physical Instruction Cache Invalidate

This section lists the *Physical Instruction Cache Invalidate* (PICI) operations that the DVM message supports. This message type is also used for Instruction Caches which are *Virtually Indexed Physically Tagged* (VIPT).

Table 8-23 shows the fixed value fields in the PICI operations.

Table 8-23 Physical Instruction Cache Invalidate operation fixed values

Field	Value	Status
Part Num	-	See Table 8-6 on page 8-325
Exception Level	0b00	Applies to all Guest OS and Hypervisor
Staged Invalidation	0b00	Reserved, set to zero
Leaf Entry Invalidation	0b0	Reserved, set to zero

Table 8-24 shows the operations supported by PICI.

Note

When VI Valid is 0b11, VI[19:12] is used as part of Physical Address (PA).

Table 8-24 Physical Instruction Cache Invalidate operations

DVMOp type	Security	VI Valid	VA Valid	Operation
0b010	0b10	0b00	0b0	Secure and Non-secure PICI all
		0b00	0b1	Secure PICI by PA without VI
		0b11	0b1	Secure PICI by PA with VI
	0b11	0b00	0b0	Non-secure PICI all
		0b00	0b1	Non-secure PICI by PA without VI
		0b11	0b1	Non-secure PICI by PA with VI

Virtual Instruction Cache Invalidate

This section shows the *Virtual Instruction Cache Invalidate* (VICI) operations.

Table 8-25 shows the fixed value fields in the VICI operation.

Table 8-25 Virtual Instruction Cache Invalidate operation fixed values

Field	Value	Status
Part Num	-	See Table 8-6 on page 8-325
Staged Invalidation	0b00	Reserved. set to zero
Leaf Entry Invalidation	0b0	Reserved, set to zero

Table 8-26 shows the operations supported by VICI.

Table 8-26 Virtual Instruction Cache Invalidate operations

Addr						
DVMOp type	Exception Level	Security	ASID valid	VMID valid	VA valid	Operation
0b011	0b00	0b00	0b0	0b0	0b0	Invalidate all. Applies to Secure and Non-secure. Applies to Hypervisor and all Guest OS.
		0b11	0b0	0b0	0b0	Invalidate all. Applies to Non-secure. Applies to Hypervisor and all Guest OS.
	0b10	0b10	0b1	0b0	0b1	Secure Invalidate by ASID and VA.
			0b0	0b1	0b0	Secure Invalidate all per VMID.
			0b1	0b1	0b1	Secure Invalidate by ASID and VA per VMID.
		0b11	0b0	0b1	0b0	Non-secure Guest OS, Invalidate all per VMID.
			0b1	0b1	0b1	Non-secure Guest OS, Invalidate by ASID and VA per VMID.
	0b11	0b11	0b0	0b0	0b1	Hypervisor, Invalidate by VA.
			0b1	0b0	0b1	Hypervisor, Invalidate by ASID and VA

8.3.4 Synchronization

This section shows the DVMSync Synchronization operation.

[Table 8-27](#) shows the fixed value fields in the Sync operation.

Table 8-27 Sync operation fixed values

Exception Level	0b00	Applies to all Guest OS and Hypervisor
DVMOp type	0b100	Synchronization message
VMID VMIDExt	0xXX	VMID not specified
ASID	0xXXXX	ASID not specified
Staged Invalidation	0b00	Set to zero
Leaf Entry Invalidation	0b0	Set to zero

Chapter 9

Error Handling

This chapter describes the error handling requirements. It contains the following sections:

- *Error types* on page 9-342
- *Error response fields* on page 9-343
- *Errors and transaction structure* on page 9-344
- *Error response use by transaction type* on page 9-345
- *Poison* on page 9-355
- *Data Check* on page 9-356
- *Use of interface parity* on page 9-357
- *Interoperability of Poison and DataCheck* on page 9-360
- *Hardware and software error categories* on page 9-361

9.1 Error types

This specification supports two types of error reporting at sub packet level. There are two types of error reporting at packet level.

The packet level error reporting types are:

Data Error, DERR

Used when the correct address location has been accessed, but an error is detected within the data. Typically, this is used when data corruption has been detected by *Error Correction Code* (ECC) or a parity check.

Data Error reporting is supported by the RespErr, Poison, and DataCheck fields in the DAT packet.

When processing of a request received by Home that is required to be propagated to the Subordinate results in a DERR, the Home must not stop propagating the request to the Subordinate.

————— **Note** —————

An error in data being evicted from Home, or received in a Snoop response as a result of the request, are examples of the request resulting in a DERR.

Non-data Error, NDERR

Used when an error is detected that is not related to data corruption. This specification does not define all cases when this error type is reported. Typically, this error type is reported for:

- An attempt to access a location that does not exist.
- An illegal access, such as a write to a read-only location.
- An attempt to use a transaction type that is not supported.

Non-data Error reporting is supported by the RespErr field in the RSP and DAT packets.

When processing of a request received by Home results in an NDERR, it is permitted, but not required, to propagate the request to the Subordinate. The Home is required to pass-back the NDERR in the response to the Requester.

9.2 Error response fields

The RespErr field is used to indicate error conditions. The RespErr field is included in both response and data packets.

Table 9-1 shows the encoding of the RespErr field. See [Responses to exclusive requests on page 6-296](#) for more details on the Exclusive Okay response.

Table 9-1 Error response field encodings

RespErr[1:0]	Name	Description
0b00	OK	Okay. Indicates that a Non-exclusive access has been successful. Also used to indicate an Exclusive access failure.
0b01	EXOK	Exclusive Okay. Indicates that either the read or write portion of an Exclusive access has been successful.
0b10	DERR	Data Error.
0b11	NDERR	Non-data Error.

A single transaction is not permitted to mix OK and EXOK responses.

A transaction with a Data response is required to include NDERR either in none or in all Data packets.

The mixing of OK and DERR responses within a single transaction is permitted.

The mixing of EXOK and DERR responses within a single transaction is permitted.

The mixing of OK and NDERR responses within a single transaction is permitted, which can occur only in transactions with both Data and Non-data responses.

The mixing of EXOK and NDERR is not permitted.

9.3 Errors and transaction structure

All transactions must complete in a protocol-compliant manner, even if they include an error response.

Error handling for a transaction that utilizes DMT is the same as the error handling for the same request without DMT.

Because there is no mechanism to propagate errors on requests or snoops, a request must not use DMT or DCT if an error is detected at the interconnect.

If the transaction contains data packets then the source of the data packets is required to send the correct number of packets, but the data values are not required to be valid.

The Resp field gives the cache states associated with a transaction and can be influenced by an error condition. See [Response types on page 4-208](#) for more details on the legal Resp field values. If a response to a transaction does not have a legal cache state, then the RespErr field must indicate a Non-data Error for all data packets.

The Resp field in a response must have the same value for every packet of a Data message regardless of whether or not there is an error condition.

A Requester that receives a response with a Non-data Error for a Snoopable request must:

- For an Allocating transaction:
 - When the start state is I, the Requester must not allocate the received data.
 - If the request was sent from a Non-Invalid state, the Requester must leave the cached copy unchanged.In both cases, the cache state must not be changed.
 - The Allocating transactions are:
 - ReadClean
 - ReadNotSharedDirty
 - ReadShared
 - ReadUnique
 - ReadPreferUnique
 - MakeReadUnique
 - CleanUnique
 - MakeUnique
- For a deallocating transaction:
 - The Requester must continue as normal, in a protocol-compliant manner.
 - The deallocating transactions are:
 - WriteBack
 - WriteEvictFull
 - Evict
 - WriteEvictOrEvict
- For Other transactions that do not change allocation:
 - The Requester must not upgrade the cache state but is permitted to downgrade it.

The cache state in a SnpResp message with a Non-data Error must be I. The Completer must invalidate local cached copies of the cache line. In addition, when the response to a Forwarding snoop results in a Non-data Error, the Snoopee must not forward data to the Requester. As a consequence, if the CompData message has already been sent to the Requester then the Snoop response to the Home must not include the Non-data Error.

9.4 Error response use by transaction type

This section defines the permitted, but not required, use of the error fields for each transaction type.

The tables that follow show the Data and Response packets associated with the following transaction types:

- [Read transactions](#)
- [Dataless transactions on page 9-347](#)
- [Write transactions on page 9-348](#)
- [Atomic transactions on page 9-350](#)
- [Other transactions on page 9-352](#)
- [Cache Stashing transactions on page 9-352](#)
- [Snoop transactions on page 9-353](#)

The following keys are used by the tables:

OK	The RespErr field must contain the OK RespErr value of 0b00.
Y	This value of RespErr is permitted.
N	This value of RespErr is not permitted.
-	Data or Response packet is not used for this transaction type.

9.4.1 Read transactions

Read transactions can contain multiple CompData data packets.

Read data which is known to be corrupt must have an appropriate Error indication where the error can be Poison, DERR, or NDERR.

When RespSepData includes a NDERR, all corresponding DataSepResp packets must be marked with NDERR.

In a Data response to a Read request, an NDERR response is only permitted either in none or in all data response packets.

————— **Note** —————

Prior to CHI Issue E, a Read transaction was permitted to include a NDERR response in some of the data responses.

[Table 9-2](#) shows the legal RespErr field values associated with Data and Response packets for Read transactions.

Table 9-2 Legal RespErr field values associated with Data and Response packets for Read transactions

Associated Data and Response packets						
Read transaction	Read Receipt	CompData				CompAck
		OK	EXOK	DERR	NDERR	
ReadNoSnp	OK	Y	Y	Y	Y	OK
ReadNoSnpSep	OK	-	-	-	-	-

Table 9-2 Legal RespErr field values associated with Data and Response packets for Read transactions (continued)

Associated Data and Response packets						
Read transaction	Read Receipt	CompData				CompAck
		OK	EXOK	DERR	NDERR	
ReadOnce ReadOnceCleanInvalid ReadOnceMakeInvalid	OK	Y	N	Y	Y	OK
ReadClean ReadNotSharedDirty ReadShared	-	Y	Y	Y	Y	OK
ReadUnique ReadPreferUnique ^a MakeReadUnique ^b	-	Y	N	Y	Y	OK

- a. EXOK response is not permitted even when Excl bit in the request is set to 1.
A response of OK in the returned data response is not to be taken as a failure of ReadPreferUnique. Failure of the exclusive sequence is only determined from the corresponding MakeReadUnique (Excl) or CleanUnique (Excl) transaction completion.
- b. Applicable only when data is returned to the Requester. See [Table 9-4 on page 9-347](#) for permitted errors when data is not returned to the Requester.

[Table 9-3](#) shows the legal RespErr field values associated with Data-only and Non-data packets for Read transactions.

Table 9-3 Legal RespErr field values associated with Data-only and Non-data packets for Read transactions

Associated Data-only and Non-data packets								
Read transaction	DataSepResp				RespSepData			
	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR
ReadNoSnp	Y	N	Y	Y	Y	N	N	Y
ReadNoSnpSep	Y	N	Y	Y	-	-	-	-
ReadOnce ReadOnceCleanInvalid ReadOnceMakeInvalid	Y	N	Y	Y	Y	N	N	Y
ReadClean ReadNotSharedDirty ReadShared	Y	N	Y	Y	Y	N	N	Y
ReadUnique ReadPreferUnique ^a MakeReadUnique ^b	Y	N	Y	Y	Y	N	N	Y

- a. A response of OK in the returned data response is not be taken as a failure of ReadPreferUnique. Failure of the exclusive sequence is only determined from the corresponding MakeReadUnique (Excl) or CleanUnique (Excl) transaction completion.

- b. Applicable only when data is returned to the Requester. See [Table 9-4 on page 9-347](#) for permitted errors when data is not returned to the Requester.

9.4.2 Dataless transactions

A DERR can be reported for a Dataless transaction when the processing of the transaction by another component encounters a data corruption error. This data error can be indicated back to the originating component, even though a transfer of data does not occur.

[Table 9-4](#) shows the Dataless transaction packets legal RespErr field values.

Table 9-4 Dataless transaction packets legal RespErr field values

Dataless transaction	Associated Response packets												CompAck
	Comp				Persist				CompPersist				
	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR	
CleanUnique	Y	Y	Y	Y	-	-	-	-	-	-	-	-	OK
MakeReadUnique ^a	Y	N	Y	Y	-	-	-	-	-	-	-	-	OK
MakeUnique	Y	N	Y	Y	-	-	-	-	-	-	-	-	OK
CleanShared	Y	N	Y	Y	-	-	-	-	-	-	-	-	-
CleanSharedPersist	Y	N	Y	Y	-	-	-	-	-	-	-	-	-
CleanSharedPersistSep	Y	N	Y	Y	Y	N	Y	Y	Y	N	Y	Y	-
CleanInvalid MakeInvalid	Y	N	Y	Y	-	-	-	-	-	-	-	-	-
Evict	Y	N	N	Y	-	-	-	-	-	-	-	-	-

- a. Applicable only when data is not returned to the Requester. See [Table 9-2 on page 9-345](#) and [Table 9-3 on page 9-346](#) for permitted errors when data is returned to the Requester.

[Table 9-5](#) shows the permitted RespErr values in responses to StashOnce transactions.

Table 9-5 Dataless Stash transaction packets legal RespErr field values

Dataless Stash transaction	Associated Response packets											
	Comp				StashDone				CompStashDone			
	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR
StashOnceUnique StashOnceShared	Y	N	Y	Y	-	-	-	-	-	-	-	-
StashOnceSepUnique StashOnceSepShared	Y	N	Y	Y	Y	N	Y	Y	Y	N	Y	Y

9.4.3 Write transactions

A Write transaction can include either a NDERR or a DERR. Errors can be signaled in both directions, from the Requester to the Completer, and from the Completer back to the Requester.

Write data which is known to be corrupt must have an appropriate Error indication where the error can be Poison or DERR.

For a Write transaction an error can be signaled from the Completer back to the Requester using either the combined CompDBIDResp or using the Comp response. It is permitted, but not required, for the Completer to signal an error even before it has observed the WriteData for the transaction and this can occur when the processing of the transaction, such as the cache lookup, encounters a data corruption error.

Table 9-6 shows the Write transaction response packets legal RespErr field values.

Table 9-6 Write transaction Response packets legal RespErr field values

Write transaction	Associated Response packets									
	DBIDResp*	Comp				CompDBIDResp				CompAck
		OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR	
WriteNoSnp	OK	Y	Y	Y	Y	Y	Y	Y	Y	OK
WriteUnique	OK	Y	N	Y	Y	Y	N	Y	Y	OK
WriteNoSnpZero WriteUniqueZero	OK	Y	N	Y	Y	Y	N	Y	Y	-
WriteBack WriteClean WriteEvictFull	-	-	-	-	-	Y	N	Y	Y	-
WriteEvictOrEvict	-	Y	N	N	Y	Y	N	Y	Y	OK

A Requester that detects an error in the write data to be sent can include an Error indication with the write data packet. This indicates that the data value is known to be corrupt.

Table 9-7 shows the Write transaction Data packets legal RespErr field values.

Table 9-7 Write transaction Data packets legal RespErr field values

Write transaction	Associated Data packets											
	WriteData				WriteDataCancel				NCBWrDataCompAck			
	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR
WriteNoSnp	Y	N	Y	N	Y	N	Y	N	Y	N	Y	N
WriteUnique	Y	N	Y	N	Y	N	Y	N	Y	N	Y	N
WriteBack WriteClean WriteEvictFull WriteEvictOrEvict	Y	N	Y	N	-	-	-	-	-	-	-	-

Table 9-8 shows the Write transaction TagMatch packet legal RespErr field values when MTE is supported on the interface of the Requester.

Table 9-8 Write transaction TagMatch packet legal RespErr field values

Write transaction	Associated response packets			
	TagMatch			
	OK	EXOK	DERR	NDERR
WriteNoSnp WriteUnique	Y	N	Y	Y
WriteBack WriteClean WriteEvictFull WriteEvictOrEvict	-	-	-	-

For permitted RespErr field values in a Combined Write transaction response:

- See [Table 9-6 on page 9-348](#) for the corresponding responses for the Write request.
 - See [Table 9-4 on page 9-347](#) for the corresponding responses for the CMO request.
- The permitted error responses in the CompCMO are the same as those in the Comp in [Table 9-4 on page 9-347](#).

9.4.4 Atomic transactions

It is permitted, but not required, for a Completer to give a Comp response before it has received all the write data associated with a transaction and has performed the required operation. This behavior is not compatible with a component that wants to signal a data error associated with the write data, and such components must use a delayed form of Comp or CompData response.

In Atomic transactions, Read data or Write data which is known to be corrupt must have an appropriate Error indication. When the error is on Read data, it can be Poison, DERR, or NDERR. When the error is on Write data, it can be Poison or DERR.

A DERR or NDERR can be signaled at the following points within a transaction:

- With the CompDBIDResp response.
- For an AtomicStore transaction, with the Comp response.
- For an AtomicLoad, AtomicSwap, and AtomicCompare transaction, with the CompData response.

———— **Note** ————

If a read data at Home due to a non-store Atomic request results in a DERR or NDERR, such an error can be propagated onto the DBIDResp or CompDBIDResp response for that request.

For Atomic transactions that are not able to complete, a NDERR must be used. The transaction structure, including all write data transfers, read data transfers, and other responses must still take place.

There is no need to specify an error associated with the execution of an atomic operation, such as overflow. All atomic operations are fully specified for all input combinations.

A transaction includes both outbound and inbound data, but only has a single Error field. For Atomic transactions, it is permitted for the Error field to indicate an error on either write data or read data. There is no mechanism supported within the transaction to differentiate between the potential different causes of an error. A fault log, or a similar structure, might be able to provide such information, but this is not a requirement of this specification.

The permitted RespErr values in Atomic transactions are an amalgamation of those permitted in Read and Write transactions.

A DERR can vary between data packets.

Table 9-9 shows the Atomic transaction Response packets legal RespErr field values

Table 9-9 Atomic transaction Response packets legal RespErr field values

Associated Response packets									
Atomic transaction	DBIDResp	Comp				CompDBIDResp			
		OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR
AtomicStore	OK	Y	N	Y	Y	Y	N	Y	Y
AtomicLoad	OK	Y	N	Y	Y	-	-	-	-
AtomicSwap									
AtomicCompare									

Table 9-10 shows the Atomic transaction Data packets legal RespErr field values.

Table 9-10 Atomic transaction Data packets legal RespErr field values								
Atomic transaction	Associated response packets							
	WriteData				CompData			
	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR
AtomicStore	Y	N	Y	N	-	-	-	-
AtomicLoad	Y	N	Y	N	Y	N	Y	Y
AtomicSwap								
AtomicCompare								

Table 9-11 shows the Atomic transaction TagMatch packet legal RespErr field values when MTE is supported.

Table 9-11 Atomic transaction TagMatch packet legal RespErr field values				
Atomic transaction	Associated response packets			
	TagMatch			
	OK	EXOK	DERR	NDERR
AtomicStore	Y	N	Y	Y
AtomicLoad				
AtomicSwap				
AtomicCompare				

9.4.5 Other transactions

This section describes the error handling requirements for the DVMOp and PrefetchTgt transactions.

DVMOp

A DVMOp transaction can include a NDERR in the Comp response. The interconnect can consolidate error responses from all the snoop responses for a DVMOp and include a single error response in the final Comp message to the Requester. The DBIDResp packet must only use the OK response. Even though the Sender of a WriteData response might not use DERR, the packet can be marked as DERR if it encounters errors during transmission. See [Interoperability of Poison and DataCheck on page 9-360](#).

Table 9-12 shows the DVM transaction Response packets legal RespErr field values.

Table 9-12 DVM transaction Response packets legal RespErr field values

DVM transaction	Associated Response packets								
	DBIDResp	Comp				CompDBIDResp			
		OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR
DVMOp	OK	Y	N	Y	Y	Y	N	Y	Y

Table 9-13 shows the DVM transaction Data packets legal RespErr field values.

Table 9-13 DVM transaction Data packets legal RespErr field values

DVM transaction	Associated Data packets			
	NCBWrData			
	OK	EXOK	DERR	NDERR
DVMOp	Y	N	Y	N

PrefetchTgt

A PrefetchTgt transaction request to a non-supporting address must be discarded.

———— **Note** —————

A component is permitted, but not required, to record and report such an error.

9.4.6 Cache Stashing transactions

If the specified Stash target does not support receiving Stash snoops, the Home must disregard the Stash hint and complete the transaction without Stashing. Examples of such Stash targets are RN-I, RN-D, legacy RN-F, or a Non-request node. In these circumstances, Home must not signal an error to the Requester. Such a wrongly specified Stash target can be attributed to a software-based error.

If the Home does not support Stash requests, it must complete the transaction in a protocol-compliant manner without signaling an error.

9.4.7 Snoop transactions

A Snoop transaction response that includes data can indicate a DERR. A Snoop transaction response that includes data can mix OK and DERR responses for different packets within the transaction.

Data, in response to a Snoop request that is known to be corrupt, must have an appropriate Error indication where the error can be Poison or DERR.

A Snoop transaction response that does not include data can indicate an NDERR.

A Snoopee that responds with an NDERR:

- Must not include data with the response.
- Must invalidate any locally cached copies.
- Must set the cache state in the response to Invalid.
- Must not forward a CompData response to the Requester in response to a Forwarding snoop. As a consequence, if the CompData message is already sent to the Requester then the Snoop response to the Home must not include a Non-data Error.

Table 9-14 shows the Snoop request Response packets legal RespErr field values.

Table 9-14 Snoop request Response packets legal RespErr field values

Snoop Transaction	Associated Data and Response packets							
	SnpResp				SnpRespData			
	OK	EXOK	DERR	NDERR	OK	EXOK	DERR	NDERR
SnpOnce	Y	N	N	Y	Y	N	Y	N
SnpClean

SnpUniqueStash								
SnpCleanShared								
SnpCleanInvalid								
SnpStashUnique	Y	N	N	Y	-	-	-	-
SnpStashShared								
SnpMakeInvalid								
SnpMakeInvalidStash								
SnpQuery								
SnpDVMOp								

It is recommended, but not required, that a DERR on a Clean cache line is dropped and the error is not propagated to the memory, nor included in the response to the Requester.

A DERR on a Dirty cache line must be propagated to the memory, and in the response to the Requester.

A DERR in response to the DataPull request is not expected to be transferred to the Comp response to the Stash request.

For a Forwarding snoop transaction, when simultaneously forwarding data to the Requester and returning Data to Home, it is permitted, but not required, for only one response to include an indication of a DERR if the other response does not encounter the error.

Table 9-15 shows the Forwarding Snoop response packets legal RespErr field values.

Table 9-15 Forwarding Snoop response packets legal RespErr field values

SnpCleanFwd								
SnpNotSharedDirtyFwd								
SnpSharedFwd								
SnpUniqueFwd								
SnpPreferUniqueFwd								

9.5 Poison

The Poison bit is used to indicate that a set of data bytes have previously been corrupted. Passing the Poison bit alongside the data in the DAT packet permits any future user of the data to be notified that the data is corrupt.

When Poison is supported:

- The DAT packet includes one Poison bit per 64 bits of data.
- Data marked as poisoned:
 - Must not be utilized by any Requester.
 - Is permitted, but not required, to be stored in caches and memory if marked as poisoned.
- The Poison value, once set, must be propagated along with the data.
- When a Poison error is detected, it is permitted, but not required, to over poison the data.
- Poison on MTE tags is not supported.

Poison must be accurate if there are any valid bytes in the 64-bit chunk. This is the Poison granularity. When all 8 bytes in the 64-bit chunk are invalid, the Poison bit can take any value.

A `Data_Poison` property is used to indicate if a component supports Poison.

———— **Note** ————

Although Poison on tags is not supported, implementations might choose to do one of the following:

- Poison associated with the data results in the tag being poisoned. Depending on the granularity of the poison associated with the tag, it might not be possible to clear the poison using the same techniques that would be used to clear poison associated with data.
- Poison associated with the data does not result in the tag being poisoned. This means that a corrupted tag might subsequently be used in an MTE Match operation, which could incorrectly fail. The rate at which this occurs should be significantly lower than the rate at which data corruption occurs.
- A mixture of approaches can be used, depending on the caching or storage structures that are used.

Other implementations are possible.

9.6 Data Check

The DataCheck field is used to detect data errors in the DAT packet.

When Data Check is supported:

- The DAT packet carries 8 DataCheck bits per 64 bits of data.
- The Data Check bit is a parity bit that generates Odd Byte parity.

Note

Interface parity optionally extends the error detection provided on the DAT channel by the DataCheck field.

The Data_Check and Check_Type properties are used to indicate if DataCheck is supported in the DAT packet. See [Check_Type on page 16-479](#) and [Data_Check on page 16-479](#).

9.7 Use of interface parity

For safety-critical applications it is necessary to detect and possibly correct, transient and functional errors on individual wires within an SoC.

An error in a system component can propagate and cause multiple errors within connected components. *Error Detection and Correction* (EDC) is required to operate end-to-end, covering all logic and wires from source to destination.

One way to implement end-to-end protection, is to employ customized EDC schemes in components and implement a simple error detection scheme between components. Between these components there is no logic and connections are relatively short. This section describes a parity scheme for detecting single-bit errors on the interface between components. Multi-bit errors may be detected if they occur in different parity signal groups. [Figure 9-1](#) shows locations where parity can be used.

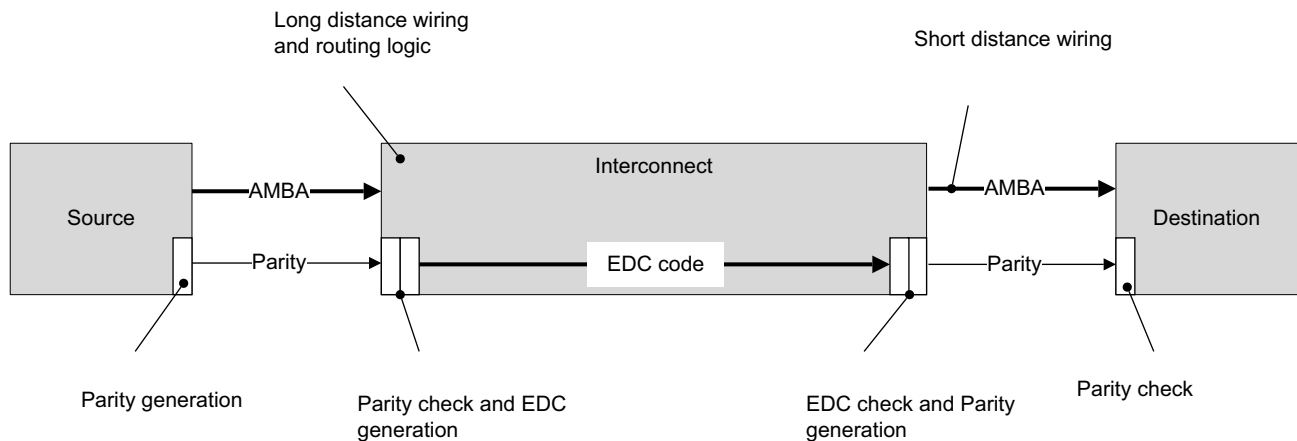

Figure 9-1 Parity use in AMBA

AMBA parity optionally extends the error detection provided on the DAT channel by the DataCheck field to cover the complete flit and control signals on all channels.

The protection scheme employed on an interface is defined by the property Check_Type. See [Interface properties and parameters](#) on page 16-478.

9.7.1 Byte parity check signals

The following attributes are common to all the check signals added for byte parity interface protection:

- Odd parity is used.
Odd parity means that check signals are added to groups of signals on the interface and driven such that there is always an odd number of asserted bits in that group.
- Parity signals covering data and payload are defined such that there are no more than 8 bits per group.
This limitation assumes that there is a maximum of 3 logic levels available in the timing budget for generating each parity bit.
- Parity signals covering critical control signals, which are likely to have a smaller timing budget available, are defined with a single odd parity bit.
- The least significant check bit of the check signal covers the least significant byte of payload.
- If the bits in a payload do not fill the most significant byte, the most significant bit of the check signal covers fewer than 8 bits.

- Check signals must be driven correctly in every cycle that the Check Enable term is True, see [Table 9-17 on page 9-359](#).
- Parity signals must be driven appropriate to all the bits in the associated payload, irrespective of whether those bits are applicable.

9.7.2 Error detection behavior

This specification is not prescriptive regarding component or system behavior when a parity error is detected. Depending on the system and affected signals, a flipped bit can have a wide range of effects. It might be harmless, cause performance issues, cause data corruption, cause security violations or deadlock. Also, an error on one signal can also cause parity failure on other signals.

When an error is detected, the receiver has options to:

- Terminate or propagate the transaction. It is permitted, but not required, to be protocol-compliant when the transaction is terminated.
- Correct the parity check signal or propagate the error.
- Update its memory or leave untouched. It is permitted, but not required, to mark the location as poisoned.
- Signal an error response through other means, for example, with an interrupt.

9.7.3 Interface parity check signals

Table 9-17 shows the parity check signals and their properties on each of the channels.

Table 9-17 Interface parity check signals

Channel	Check signal	Signals covered	Check signal width	Check granularity	Check enable
Common	SYSCOREQCHK	SYSCOREQ	1	1	RESETn == 1
	SYSCOACKCHK	SYSCOACK	1	1	RESETn == 1
Common	TXSACTIVECHK	TXSACTIVE	1	1	RESETn == 1

	DATFLITVCHK	DATFLITV	1	1	RESETn == 1
	DATFLITCHK	DATFLIT	$\text{ceil}(D/8)^d$	1 to 8	DATFLITV == 1
	DATLCRDVCHK	DATLCRDV	1	1	RESETn == 1

a. R = Request flit width. See [Request flit](#) on page 13-418.

b. T = Response flit width. See [Response flit](#) on page 13-420.

c. S = Snoop flit width. See [Snoop flit](#) on page 13-421.

d. D = Data flit width. See [Data flit](#) on page 13-422.

9.8 Interoperability of Poison and DataCheck

If the recipient of a Data packet does not support the Poison and DataCheck features then the interconnect must enumerate and convert, as necessary, the Poison and DataCheck error responses to a DERR in the DAT packet.

If support for the Poison and DataCheck features is not similar across an interface, then the following rules apply:

- Poison must be mapped to DataCheck or DERR if Poison is not supported across the interface. At such an interface, Poison is expected but not required to be mapped to DataCheck instead of DERR, if DataCheck is supported.
When converting from Poison to DataCheck, when an 8-byte chunk is marked as Poisoned, all 8 bits of DataCheck corresponding to that chunk must be manipulated to generate a parity error.
- DataCheck must be mapped to Poison or DERR if DataCheck is not supported across the interface. At such an interface, DataCheck is expected but not required to be mapped to Poison instead of DERR, if Poison is supported.
When converting from DataCheck to Poison, if one or more DataCheck bits in a given 8-byte chunk generates a parity error, then the Poison bit corresponding to that chunk must be set.

Note

The difference between the handling of Poison and DERR is that a Poison error in a received data packet is typically deferred by the receiver, but a DERR error is typically not deferred by the receiver.

It is sufficient for the Sender of a data packet that detects a Poison error to indicate this in the Poison bits. It is not a requirement that the Sender sets the RespErr field value to DERR.

It is sufficient for the Sender of a data packet that detects a DataCheck error to indicate this in the DataCheck field and is not required to set RespErr field value to DERR.

As Poison and DataCheck fields are independently set, one type of error does not require setting of the other.

In a Data packet that has the RespErr field value set to DERR or NDERR, the value of the Poison and DataCheck fields are inapplicable and can take any value.

9.9 Hardware and software error categories

This specification defines two error categories: a software-based error and a hardware-based error.

9.9.1 Software-based error

A software-based error occurs when multiple accesses to the same location are made with incorrect or mismatched Snoopable or Memory attributes. See [Mismatched Memory attributes on page 2-140](#).

A software-based error can cause a loss of coherency and the corruption of data values. It is required that the system does not deadlock for a software-based error, and that transactions always progress through a system in a timely manner.

A software-based error, for an access within one 4KB memory region, must not cause data corruption within a different 4KB memory region.

For locations held in Normal memory, the use of appropriate stores and software cache maintenance can be used to return memory locations to a defined state.

When accessing a peripheral device, the correct operation of the peripheral cannot be guaranteed. The only requirement is that the peripheral continues to respond to transactions in a protocol-compliant manner. The sequence of events that might be required to return a peripheral device that has been accessed incorrectly to a known working state is IMPLEMENTATION DEFINED.

9.9.2 Hardware-based error

A hardware-based error is defined as any protocol error that is not a software-based error.

———— Caution ————

If a hardware-based error occurs, recovery from the error is not guaranteed. The system might crash, lock-up, or suffer some other non-recoverable failure.

Chapter 10

Quality of Service

This chapter describes the mechanisms in the CHI protocol to support *Quality of Service* (QoS). It contains the following sections:

- [Overview on page 10-364](#)
- [QoS priority value on page 10-365](#)
- [Repeating a transaction with higher QoS value on page 10-366](#)

10.1 Overview

A system might utilize a QoS scheme to achieve:

- A guaranteed maximum latency for transactions in a particular stream.
- Minimum bandwidth guarantees for a stream of requests.
- Best effort value of bandwidth and latency provided to requests of a particular stream.

The low latency, or guaranteed throughput requirements, required to meet system QoS demands are primarily the responsibility of the transaction end points with support from the intermediate interconnect. The protocol supports this by defining a QoS priority value for packets and controlling request flow using a defined credit mechanism.

10.2 QoS priority value

A 4-bit value is used to prioritize the processing of the packets at protocol nodes and within the interconnect. The *QoS Priority Value* (PV) for packets is assigned by the source of the transaction. In typical usage models, this value depends on the source type and the class of traffic with ascending values of QoS indicating a higher priority level. The source might also dynamically vary this value, depending on some accumulated latency and required throughput metric.

10.3 Repeating a transaction with higher QoS value

When a transaction has been sent with a particular QoS value, it is permitted, but not required, to send the same transaction again with a different QoS value, typically higher. The Completer is required to handle this situation as multiple different requests.

In this instance, if one of the transactions receives a RetryAck response, it is permitted, but not required, to cancel the transaction and return the credit. See [Credit Return on page 2-155](#).

Chapter 11

System Debug, Trace, and Monitoring

This chapter describes mechanisms that provide extra support for the debugging and tracing of systems, and the monitoring of systems to enhance performance. It contains the following sections:

- [Data Source indication on page 11-368](#)
- [SLC replacement hint on page 11-371](#)
- [MPAM on page 11-373](#)
- [Completer Busy on page 11-375](#)
- [Trace Tag on page 11-376](#)

11.1 Data Source indication

It is permitted, but not required, that the Completer of a Read request to specify the source of the data. The source is specified in the DataSource field of the CompData, DataSepResp, SnpRespData, and SnpRespDataPtl responses. DataSource field value is valid even in data responses with error.

The DataSource field can also be used to transport information to bias SLC replacement policy. See [SLC replacement hint on page 11-371](#).

11.1.1 DataSource value assignment

The DataSource values must be assigned as follows:

- Fixed values are used for DataSource when data comes from memory and are used to indicate the following:
 - **0b0110** PrefetchTgt memory prefetch was useful.
Read data was obtained from the Subordinate with lower latency as the PrefetchTgt request already read or initiated a read of data from memory.
 - **0b0111** PrefetchTgt memory prefetch was not useful.
Read request went through a complete memory access and therefore did not have any latency reduction due to the PrefetchTgt request sent earlier.
The precise reason for signaling that a prefetch was not useful is IMPLEMENTATION DEFINED.
- Note**
- There are several reasons why the PrefetchTgt request might not be useful. Examples are that the prefetch was dropped by the Subordinate, the data obtained by the prefetch was replaced in the buffer, or the Read request arrived at the Subordinate before the prefetch.
- For a response from a cache, not memory, the DataSource value is IMPLEMENTATION DEFINED.
It is recommended, but not required, to have settings for DataSource in these cases.
A component is permitted, but not required, to have software programmability to override the DataSource value to:
 - Change the groupings to more suitable specific configuration settings.
 - Change the values where the values are not correct.
 - A Completer is permitted to not support sending a useful DataSource value:
 - The Completer, except for a memory SN-F, must return a 0b0000 value.
 - A memory SN-F component must return 0b0111 as a default value.Such exceptions must be understood by the system.

11.1.2 Crossing a chip-to-chip interface

It is the responsibility of the chip interface module, if one exists, to map DataSource values in the incoming data packets to different values to identify that the response came from the remote chip caches.

Example approaches that the chip interface module might take are:

- Group the remote caches into a single encoding, as [Figure 11-1 on page 11-369](#) shows.
- Have a maximum size of an eight entry table, to remap the implementation values of the DataSource field in the incoming data packet to new values.

Suggested DataSource values

Figure 11-1 shows an example multichip configuration and the suggested mapping of DataSource values to different components in the system:

- Each chip in the system has two processors per cluster, with a three-level cache hierarchy.
- The cache in the chip-to-chip interface module is identified as part of the interconnect caches.
- All the caches in the remote peer chip are grouped.
- A non-memory component that is not programmed to identify itself as the source of data can return the default value of 0b0000.

Table 11-1 lists the suggested DataSource encodings.

Table 11-1 Suggested DataSource value encodings

DataSource	Suggested mapping
0b0000	Non-memory default. Source does not support sending a useful DataSource value.
0b0001	Peer processor cache within local cluster
0b0010	Local cluster cache
0b0011	Interconnect cache
0b0100	Peer cluster caches
0b0101	Remote chip caches
0b1010	Local cluster cache, unused prefetch ^a
0b1011	Interconnect cache, unused prefetch ^a

a. New in CHI Issue E. See *SLC replacement hint* on page 11-371.

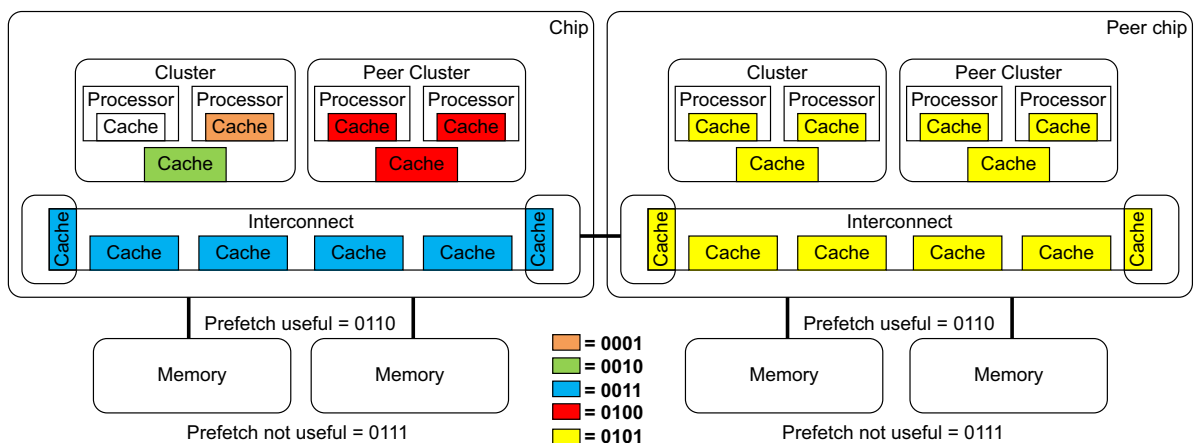

Figure 11-1 Suggested DataSource values

11.1.3 Example use cases

Two examples of how DataSource information can be used by a Requester are:

- To determine the usefulness of a PrefetchTgt transaction in initiating a memory controller prefetch.
 - By monitoring the DataSource value in the data returned from the memory SN-F, the Requester can determine the usefulness of sending PrefetchTgt requests and can modulate the rate, and the sending, of PrefetchTgt requests.
- Can be used by performance profiling and debug software to evaluate and optimize the data sharing pattern.

11.2 SLC replacement hint

The purpose of this feature is to forward cache replacement hints from the Requesters to the caches in the interconnect, the *System Level Caches* (SLC). Typically, a Request Node has the best knowledge of the utility of a cache line. An SLC that is informed of this knowledge can use it to bias its own replacement algorithms and manage cache line replacement in a more efficient manner.

11.2.1 Characteristics

Although the replacement information is most useful in CopyBack requests, this feature is not restricted to CopyBack transactions alone. It is extended to all requests from the Request Node to HN-F, except for the following:

- Atomics
- Stash transactions when StashNIDValid is 1
- PrefetchTgt
- PCrdReturn
- DVMOp

This feature is supported by a 7-bit field called SLCRepHint that is included in the REQ channel. SLCRepHint includes two subfields, a 3-bit Replacement field and a 1-bit UnusedPrefetch field.

Figure 11-2 shows the placement of the SLCRepHint subfields.

Figure 11-2 SLCRepHint subfield placement

The SLCRepHint field shares the same REQ packet location as ReturnNID and StashNID. When the node ID widths are greater than 7-bit and the field is used as SLCRepHint then the unused bits of the shared field must be set to zero.

Table 11-2 shows the encoding of the UnusedPrefetch subfield.

Table 11-2 UnusedPrefetch subfield encoding

UnusedPrefetch	Description
0	The cache line might have been used since being fetched.
1	The cache line was not used since being fetched.

Note

A Request Node that does not track the usage of the cache line can set the UnusedPrefetch bit value to zero.

The SLCRepHint field is only applicable in requests from a Request Node to HN-F.

The field is inapplicable in requests from the Request Node to HN-I and the Home Node to the Subordinate Node. The field can take any value.

[Table 11-3](#) shows the suggested Replacement subfield encodings and their meaning.

Table 11-3 Suggested Replacement subfield encodings

Replacement[2:0]	Description
0b000	No recommendation (default)
0b100	Most likely to be used again
0b101	More likely to be used again
0b110	Somewhat likely to be used again
0b111	Least likely to be used again
0b011 - 0b001	Unused

11.3 MPAM

Memory system Performance Resource Partitioning and Monitoring (MPAM) is a mechanism to efficiently utilize the memory resources among users and to monitor the utilization of those resources. The resources are partitioned among users by *Partition ID* (PartID) and *Performance Monitoring Group* (PerfMonGroup). A Requester that supports MPAM includes in each request it sends a label, identifying the partition to which it belongs, together with the performance monitoring group within that partition. The Home or the Subordinate use this information to allocate their resources to this request. Support for MPAM on an interface is defined by the MPAM_Support property, See [MPAM_Support](#) on page 16-479.

The MPAM field is applicable only in the REQ and SNP channels:

- On the REQ channel, when a sender does not want to use MPAM for a request, the MPAM values must be set to default settings. See [Default values for MPAM subfields](#) on page 11-374.
- On the SNP channel, MPAM values are only applicable in Stash snoops.
In Non-stash type snoops, MPAM values are inapplicable and must be set to default values.

Field width is either 0 bits or 11 bits:

- The width is zero on interfaces that do not support MPAM.
- The width is 11 bits on interfaces that support MPAM. The field is further divided into the subfields:
 - PartID = 9 bits
 - PerfMonGroup = 1 bit
 - MPAMNS = 1 bit

Figure 11-3 shows the allocation of the MPAM field bits.

Figure 11-3 MPAM subfields bit allocation

It is IMPLEMENTATION DEFINED how the Receiver uses the MPAM field values.

11.3.1 MPAMNS

A Non-secure bit in the MPAM field, this is in addition to and different from the NS bit of the request.

The polarity of the MPAMNS bit encoding is the same as that of the NS bit.

Table 11-4 shows the MPAMNS encodings.

Table 11-4 MPAMNS encodings

MPAMNS	Description
0	Secure partition
1	Non-secure partition

All four combinations of values of MPAMNS and NS are permitted.

———— Note ————

This change is applied retrospectively to the CHI Issue D and Issue E.a specification.

11.3.2 MPAM value propagation

The Receiver is permitted, but not required, to support the full range of partitions and performance monitor groups received in the request. It is expected that during the system discovery and configuration process the capabilities of the system are discovered and the range of partitions and performance monitor groups that are used will match the capabilities of the system.

MPAM field values must be propagated onto an interface that supports MPAM.

It is permitted, but not required, to propagate MPAM field values onto an interface that does not support MPAM.

[Table 11-5](#) shows the default values for MPAM fields when not supported or not propagated.

Table 11-5 Default values for MPAM subfields

MPAM field	Value
PerfMonGroup	0
PartID	0
MPAMNS	<ul style="list-style-type: none">Same as NS value in the request messageSame as NS value in the snoop message

11.3.3 Stash transaction rules

MPAM values in Stash snoops must be the same as in the request that generated the snoops.

For responses to Stash snoops, when the response includes a DataPull request, the Home must assume the MPAM values in the DataPull request are the same as in the original Stash request.

11.3.4 Request to Subordinate rules

MPAM values in a request to the Subordinate, where the request is generated by a request to the Home, must be the same as the MPAM values in that request to the Home.

11.4 Completer Busy

The Completer Busy indication is a mechanism for the Completer of a transaction to indicate its current level of activity. This signaling provides additional information to a Requester on how aggressive it can be in generating speculative activity to improve performance.

CBusy Completer Busy. A 3-bit field that is applicable in the appropriate DAT and RSP packets.
When separate Data and Comp responses are used for a single Read request, the Busy indication in each response can be independently set.

The CBusy field is not applicable in:

- NCBWrData
- NCBWrDataCompAck
- CBWrData
- WriteDataCancel
- CompAck

———— Note ————

DataSource can be used as a qualifier to the Completer Busy indication such that some data sources, for example a Forwarding snoop, do not influence the busy indication.

11.4.1 Use case

It is IMPLEMENTATION DEFINED how a CBusy indication is set by the Completer nor how it should be interpreted by a Requester. However, it is recommended that implementations consider mechanisms to avoid a few busy Completers among many skewing the results.

Example use case

The following is an example encoding of the CBusy field.

CBusy[2] When asserted, this indicates multiple cores are actively making requests.

CBusy[1:0] Indicates the degree of fullness of the tracker at the Completer as:

- 00 = Less than 50% full
- 01 = Greater than 50% full
- 10 = Greater than 75% full
- 11 = Greater than 90% full

The prefetcher at the Requester can use the CBusy field values and fine-tune the prefetcher.

Table 11-6 shows the prefetcher mode that is determined by the value of CBusy.

Table 11-6 Prefetcher mode that is determined by CBusy

CBusy[2]	CBusy[1:0]	Prefetcher mode
1	11	Disable inaccurate prefetchers.
Can take any value	10	Very conservative mode on inaccurate prefetchers.
1	01	Moderately aggressive mode on inaccurate prefetchers.
Can take any value	00	Fully aggressive mode on inaccurate prefetchers.

11.5 Trace Tag

This specification includes a TraceTag bit per channel that provides enhanced support for debugging, tracing, and performance measurement of systems.

11.5.1 TraceTag usage and rules

The rules for when to set and how to propagate TraceTag bit values are:

- The TraceTag bit can be set by the transaction initiator or an interconnect component.
- A component that receives a packet with TraceTag bit set in every received packet must preserve and reflect the value back in any response packet or spawned packet generated in response to the received packet. Otherwise, the TraceTag bit in response and spawned packet can take any value. This requirement is true only when the TraceTag bit in the response packet is applicable. Examples of pairs of such response and received packets are CompAck in response to multiple CompData packets and Snoop response to the pair of two DVMOp packets.
- If a received packet spawns multiple responses, such as a Write request resulting in separate Comp and DBIDResp responses or a Read request generating separate DataSepResp and RespSepData responses, all such spawned responses are required to have the TraceTag bit set if the spawning packet has the TraceTag bit set. If the spawning packet does not have the TraceTag bit set, the value of the TraceTag bit in a spawned packet is independent of the value of the bit in other related spawned packets.
- If a component can receive multiple packets that are associated with a single transaction, then for each packet that it, in turn, generates, the TraceTag value is only required to be set if it is set in the associated received packet. For example:
 - A Write transaction flow at the Request Node might have write data and CompAck as two responses for received packets DBIDResp and Comp respectively. As CompAck is in response to the received Comp only, its TraceTag bit value is only required to depend on the TraceTag bit value in the Comp packet and similarly for the write data and DBIDResp Response-Received Packet pair.
A request that receives separate DataSepResp and RespSepData responses and generates a CompAck, is only required to have the TraceTag bit set in CompAck if RespSepData has the TraceTag bit set.
 - The TraceTag bit in the NCBWrDataCompAck response from the Request Node must be set if either one of Comp or DBIDResp that caused the WriteData response have the TraceTag bit set.
- When an interconnect receives a packet with the TraceTag bit set, it must preserve the value and not reset the value.

———— **Note** ————

- Propagating the value of the TraceTag bit on a resulting cache eviction is IMPLEMENTATION DEFINED.
- The precise mechanism to trigger and utilize the TraceTag bit is IMPLEMENTATION DEFINED.
- It is expected that the TraceTag bit will be limited to single system-wide use at any time.

Some of the ways the trace tag mechanism can be used are:

- Debug, by tracing transaction flows through the system.
- Performance counting
- Latency measurement

Examples, not an exhaustive list, of Request-Response pairs are:

- A Snoop response, with or without data, in response to a Snoop request.
- A Snoop response in response to a SnpDVMOp request.
- Data response from the Subordinate Node in response to a Read request.
- Spawned requests from HN-F:
 - Snoops generated in response to a request from the Request Node.
 - Request to SN-F generated in response to a request from the Request Node.
- Spawned request from HN-I:
 - Read or Write request to SN-I generated in response to a request from the Request Node.
- A CompAck from the Request Node in response to CompData, Comp, or RespSepData.

- A RetryAck response from the Home Node or the Subordinate Node to any request.
 - A ReadReceipt response from the Home Node or the Subordinate Node to a Read request or from the Subordinate Node to a ReadNoSnPSep request.
 - A DBIDResp response to a Write request.
-

Chapter 12

Memory Tagging

This chapter describes the Memory Tagging mechanism and contains the following sections:

- *Introduction* on page 12-380
- *Message extensions* on page 12-381
- *Tag coherency* on page 12-382
- *Read transaction rules* on page 12-383
- *Write transactions* on page 12-386
- *Dataless transactions* on page 12-388
- *Atomic transactions* on page 12-389
- *Stash transactions* on page 12-390
- *Snoop requests* on page 12-391
- *Home to Subordinate transactions* on page 12-393
- *Error response* on page 12-394
- *Requests and permitted tag operations* on page 12-396
- *TagOp field use summary* on page 12-398

12.1 Introduction

The *Memory Tagging Extension* (MTE) is a mechanism that is used to check the correct usage of data held in memory. When a memory location is allocated for a particular use, it can be also assigned a memory tag. This memory tag is held alongside that data in memory and is referred to as the Allocation Tag. When the memory location is later accessed, the Requester uses both the address of the location and the tag value that it believes is associated with the location. This tag is referred to as the Physical Address Tag or Physical Tag.

For any access where tag checking is enabled, the Physical Tag is checked against the Allocation Tag. The access always progresses as normal, and the result of the tag check determines whether or not an error condition is signaled.

This mechanism ensures that a memory access is for its expected purpose, rather than an erroneous or malicious access. It can be used at runtime to identify many common programming memory errors, such as buffer-overflow and use-after-free.

The memory tag consists of a 4-bit tag associated with each aligned 16 bytes of data in memory.

The following behavior is supported:

- Memory tagging is permitted only in requests to Normal WriteBack memory.
- Read transactions have an indication in the transaction request that determines whether the Allocation Tag value must be returned alongside the data.
Checking of the returned Physical Tag against the Allocation Tag is performed by the Requester.
In the case where a cache holds the data value, but does not hold the Allocation Tag value, then a Read transaction that returns both data and tag must be performed. The data returned is not required to be valid.
- Read requests that require tags to be fetched must not use Forwarding snoops.
- StashOnce transactions that request Allocation Tags.
The Allocation Tags are expected to be stashed along with the stashing of data.
- Write transactions that have a Physical Tag supplied alongside the write data that must be checked against the Allocation Tag.
Checking of the Physical Tag against the Allocation Tag is performed by the Completer. In the case of a mismatch a notification of the failure is required.
- Write transactions that update the Allocation Tag to a new value.
These Write transactions typically update the data at the same time. However, it is permitted to have no BE asserted so that only the tag is updated.
- Write transactions which pass a Dirty or Clean cache line to a downstream cache or memory controller without either updating or checking the tags.
These Write transactions always include data and provide an indication whether the Allocation Tag value is also being passed with the data.
- Snoop transactions that return data can also return the associated Allocation Tag.
If the tags are Dirty, they must be returned. If the tags are Clean, then returning them is optional.
- Cache Maintenance Operations must operate on both the data and the corresponding memory tags.

12.2 Message extensions

The following extensions to the CHI message definitions are used to support Memory Tagging:

- Tag** Provides sets of 4-bit tags, each associated with an aligned 16 bytes of data.
- Applicable on the DAT channel only.
 - Size is Data_Width/32 bits.
- See [Tag on page 13-443](#).
- TU** Tag Update. Indicates which of the Allocation Tags must be updated.
- Applicable on the DAT channel only.
 - Size is Data_Width/128 bits.
- See [Tag Update, TU on page 13-443](#).
- TagOp** Tag Operation. Indicates the operation to be performed on the tags present in the corresponding DAT channel.
- Applicable on the REQ, DAT, and RSP channels.
 - Size is 2 bits.
 - [Table 12-1](#) shows the value encodings.

Table 12-1 TagOp encoding and Tag operations

TagOp[1:0]	Tag operation
0b00	Invalid
0b01	Transfer
0b10	Update
0b11	Match or Fetch

See [Tag Operation, TagOp on page 13-443](#).

Note

For clarity, in the following sections TagOp values are italicized to differentiate them from data and cache line values.

12.3 Tag coherency

This section summarizes the tag coherency features.

Allocation Tags that are cached are kept hardware coherent. The coherence mechanism is the same as data coherence.

Applicable tag cached states are: Invalid, Clean, and Dirty. A cache line that is either Clean or Dirty is Valid.

Constraints on the combination of data cache state and tag cache state are:

- Tags can be Valid only when data is Valid.
- Tags can be Invalid when data is Valid.
- When a cache line is in a Unique state, it applies to both data and tags.
- When a cache line is in a Shared state, it applies to both data and tags.
- When a cache line with Dirty tags is evicted then:
 - Both data and tags must be treated as Dirty.
 - The tags must be either written back to memory or passed Dirty [_PD] by Home to another cache.
- When Clean tags are evicted from a cache, they can be sent to other caches or dropped silently.
- When Clean tags are evicted with Dirty data, Clean tags can be transferred downstream of PoC along with Dirty data.

12.4 Read transaction rules

A read can optionally fetch tags along with the data. The need to return tags along with read data is determined from the value of TagOp in the request.

12.4.1 TagOp values

When TagOp value in the request is *Transfer*:

- Tags are required to be returned along with the data.
- The state of the returned tags must be the appropriate permitted cache state for the request being used.
- The number of tags to be returned is determined by the size of Data that is returned. For all Snooperable requests four tags per access must be returned.
- When required by the access, matching of Physical Tags against the Allocation Tags that are received along with read data is done at the Requester.

When TagOp value in the Request is *Fetch*:

- Tags are required to be returned along with data.
- Returned data is not required to be valid. The Requester must ignore the received data irrespective of the tag match result.
- All tags corresponding to a cache line must be returned.
- The state of the returned tags must be Clean or Dirty.
- If Dirty tags are returned, they must be preserved, unless updated, and written back to memory.

When TagOp value in the request is *Invalid*:

- It is permitted, but not required, that tags are returned along with the data.
- If tags are returned along with the data, then they must be Clean.

Converting tags from Shared to Unique

To update either the data or the tags or both, when both the data and the tags are present at the Requester in Shared state and the Requester requires to move the cache line to a Unique state the MakeReadUnique transaction with a TagOp value of *Transfer* is expected to be used. The Requester is permitted to use ReadUnique with a TagOp value of *Transfer*.

Fetching tags when Data is present

If a Requester has a cached copy of a cache line, with data Valid but Allocation tags are not Valid and the Requester requires a Tag Match to be performed then the Requester must use a Read request to fetch the required tags. The type of the Read request and TagOp value in the request depends on:

- The operation being performed by the Requester, that is, a Load or a Store operation.
- The size of the Store operation.
- The target memory location.

A Requester in the above scenario must use:

- ReadClean with *Transfer* if the operation is a Load operation. The request can be sent from any initial data state. The initial MTE tag state is expected to be invalid but is permitted to be any state. See [Table 4-34 on page 4-221](#) for Requester cache state transitions.
- ReadUnique with *Transfer* if the operation is a Store operation. The request can be sent from any initial data state. The initial MTE tag state is expected to be invalid but is permitted to be any state. ReadUnique, irrespective of the existence of MTE can be sent from any initial data state.

- ReadNoSnp with *Fetch* if the target memory location is Non-snoopable and the Requester guarantees to write a full cache line irrespective of the Tag Match result. The returned data must be dropped. The returned data is not required to be valid. Clean tags must be returned. All tags within the cache line must be Valid.
- ReadUnique with *Fetch*, if the target memory location is Snoopable and the Requester guarantees to write a full cache line irrespective of result of the Tag Match result. The returned data must be dropped. The returned data is not required to be valid. Clean or Dirty tags must be returned. All tags within the cache line must be Valid.

When responding to a ReadClean, a Home that uses a Snoop Filter to track the cached state at the Requester, must not downgrade the state of the cache line in the Snoop Filter based on the state in the response to the Requester.

Note

In prior issues of this specification, I and UCE were the only permitted initial cache line states for the ReadClean transaction. The Home that uses a Snoop Filter to track the cached states was permitted to set the state of the cached line based on the state in the response.

Permitted responses and tag state

The data and state of the cache line received with the Allocation Tags must be appropriately handled to not break coherency.

When the request TagOp value is *Transfer*, the permitted response field values are:

- *Transfer*. Indicates the returned tags are Clean.
- *Update*. Indicates the returned tags are Dirty. Data response must pass Dirty [_PD].

When the request TagOp value is *Fetch*, the permitted response field values are:

- *Transfer*. Indicates the returned tags are Clean.
- *Update*. Indicates the returned tags are Dirty. Data response must pass Dirty [_PD].

When the request TagOp value is *Invalid*, the permitted response field values are:

- *Invalid*. Indicates the returned tags are Invalid.
- *Transfer*. Indicates the returned tags are Clean.

When the TagOp value in Read data is invalid, TU must be all zeros. Tag is inapplicable and can take any value.

When data and response are separately sent in a Read transaction, the TagOp field is only applicable in the Data-only message. It is inapplicable in the Non-data response message and must be set to zero.

The cache state that the tags must be held in is consistent with the type of the Read request:

- For all Read requests with a TagOp value of *Invalid*, Invalid or Clean tags must be returned.
- For ReadNoSnp with a TagOp value of *Transfer* or *Fetch*, Clean tags must be returned.
- For ReadOnce and ReadClean with a TagOp value of *Transfer*, Clean tags must be returned.
- For ReadNotSharedDirty with a TagOp value of *Transfer*, Clean or Dirty tags must be returned. Dirty tags are permitted to be returned only if the cache line state is Unique.
- For ReadShared with a TagOp value of *Transfer*, Clean or Dirty tags must be returned.
- For ReadUnique with a TagOp value of *Transfer* or *Fetch*, Clean or Dirty tags must be returned. The returned cache line state must be Unique.
- For MakeReadUnique with a TagOp value of *Invalid*, Invalid or Clean tags must be returned. Clean tags are only permitted in responses with data.
- For MakeReadUnique with a TagOp value of *Transfer*, if data is included in the response then Clean or Dirty tags must be returned. To issue a MakeReadUnique with a TagOp value of *Transfer*, it is required that the Requester has copies of both the data and the tags.
 - Clean tags are only permitted if data is included in the response.

- Dirty tags are only permitted when the response is transferring the responsibility of updating Dirty data, that is the response includes [UD_PD].
- In the case where Dirty tags are returned, the cache line returned must include pass Dirty [_PD].

When MTE is not supported for the targeted address, the response must use TagOp of *Invalid*.

For an Exclusive access sequence, it is important that the fetching of tags must avoid any form of request that will Invalidate other copies of the cache line before the Exclusive Store transaction is performed. This is typically achieved by fetching tags at the same time the Exclusive Load transaction is performed.

12.4.2 Permitted initial MTE tag states

Table 12-2 shows the permitted initial data state along with tag state for different Read transactions and permitted TagOp value in the corresponding request. The combination of tag and data states must obey the coherency rules described in [Tag coherency on page 12-382](#).

Table 12-2 Permitted initial Tag states and request TagOp values in Read transactions

Request	TagOp	Data state	Tag state
ReadNoSnP	<i>Invalid, Transfer, Fetch</i>	I	Invalid
ReadOnce	<i>Invalid, Transfer</i>	I, UCE	Invalid
ReadNotSharedDirty			
ReadShared			
ReadClean	<i>Invalid</i>	I, UCE	Invalid
		I, UCE	Invalid
	<i>Transfer</i>	SC, UC	Invalid, Clean
		SD, UD	Invalid, Clean, Dirty
ReadPreferUnique	<i>Invalid, Transfer</i>	I, UCE	Invalid
		SC	Invalid, Clean
		SD	Invalid, Clean, Dirty
ReadUnique	<i>Invalid, Transfer, Fetch</i>	I, UCE	Invalid
		SC, UC	Invalid, Clean
		SD, UD	Invalid, Clean, Dirty
MakeReadUnique	<i>Invalid</i>	SC	Invalid, Clean
		SD	Invalid, Clean, Dirty
	<i>Transfer^a</i>	SC	Clean
		SD	Clean, Dirty

a. The requester has copies of both the data and the tags.

12.5 Write transactions

Different fields to support MTE are distributed between the Request and Data message of a Write transaction. The TagOp field, which indicates the operation to be performed on the tags in the WriteData message, is included in both the Request and WriteData message. The Request also includes the TagGroupID field to provide an identifier for the pass/fail response for a request that requires a Tag Match operation.

———— Note ————

The use of the TagGroupID field is IMPLEMENTATION DEFINED, typically it can be used to identify the Exception level and TTBR which a response relates to.

The TagOp value in the WriteData message is typically the same as the value in the Request message, except when either the write data is snooped out or the write is canceled. Whether or not to perform a Tag Match must be decided based on the TagOp value in the WriteData, when the TagOp values in the WriteData and Write request are different.

The WriteData message also includes a Tag Update (TU) bit per tag, which is applicable when TagOp is *Update*.

12.5.1 Permitted TagOp values

This section describes the permitted WriteData TagOp values for each of the permitted TagOp values in the Write request message.

When the TagOp field in the Request is *Invalid*, the Memory Tagging fields in the WriteData must be set to zero and ignored by the Completer.

When the TagOp field in the Request is *Transfer*, the TagOp field in the WriteData can be:

- *Transfer*: The Tags are Clean and must be handled appropriately by the Completer.
- *Invalid*: This is possible only if either the cached copy is invalidated, or the Write transaction is canceled.

In a WriteClean transaction where the Request TagOp is *Transfer*, the TagOp in the Write data is not permitted to be changed to *Update*.

When the TagOp field in the request is *Update*, the TagOp field in the WriteData can be:

- *Update*: The Dirty tags must be cached or written to memory.
- *Transfer*: The Tags are Clean. This is possible if the Dirty tags have been snooped out.
- *Invalid*: This is possible only if either the cached copy is invalidated or the Write transaction is canceled.

When the TagOp field in the Request is *Match* the TagOp field in the WriteData can be:

- *Match*: The appropriate Tag Match must be performed at the Completer.
- *Invalid*: This is possible only if the Write transaction is canceled.

12.5.2 TagOp, TU, and tags relationship

This section describes the relationship between TagOp, TU, and tags in different Write transactions:

- For all Write requests with TagOp *Invalid*, the Memory Tagging fields must be set to zero and ignored by the Completer.
- For WriteBackFull and WriteCleanFull with TagOp:
 - *Transfer*: Clean tags must be returned. TU bits are inapplicable and must be set to zero.
 - *Update*: All TU bits must be asserted.
 - *Match*: Not permitted.
- For WriteBackPtl with TagOp:
 - *Transfer*: Not permitted.
 - *Update*: Not permitted.
 - *Match*: Not permitted.

- For WriteNoSnpFull with TagOp:
 - *Transfer*: TU bits are inapplicable and must be set to zero. Clean tag transfer is permitted from the Request Node to the Home Node as well as the Home Node to the Subordinate Node.
 - *Update*: All TU bits must be asserted.
 - *Match*: TU bits are inapplicable and must be set to zero.
- For WriteUniqueFull and WriteUniqueFullStash with TagOp:
 - *Transfer*: Not permitted.
 - *Update*: All TU bits must be asserted.
 - *Match*: TU bits are inapplicable and must be set to zero.
- For WriteNoSnpPtl, WriteUniquePtl and WriteUniquePtlStash with TagOp:
 - *Transfer*: Not permitted.
 - *Update*: Any combination of TU and BE bits, including none or all, can be asserted.
 - *Match*: TU bits are inapplicable and must be set to zero. Tag Match must be performed for only those tags that have at least one corresponding BE bit asserted.
A Tag Match must not be performed when all BE bits are set to zero.
- For WriteEvictFull, WriteEvictOrEvict and with TagOp:
 - *Transfer*: Clean tags must be returned. TU bits are inapplicable and must be set to zero.
 - *Update*: Not permitted.
 - *Match*: Not permitted.
- For WriteNoSnpZero and WriteUniqueZero, only TagOp *Invalid* is permitted.

For a Write request with a TagOp of *Match* the tags within the size wrap boundary can take any value, and the tags outside of size are inapplicable and can also take any value.

In the WriteDataCancel Write data response, irrespective of the TagOp value in the Write request, the MTE fields are inapplicable and must be set to zero.

In Write data, with TagOp *Invalid*, all the TU bits and all the Tag bits must be set to zero.

12.6 Dataless transactions

MakeUnique is the only Dataless transaction that supports the use of the TagOp field. In all other Dataless transactions, the TagOp field is inapplicable and must be set to all zeros.

The TagOp value in MakeUnique request can be *Invalid* or *Update* only. A Request TagOp value of *Update* is an indication that the Requester will update the tags along with data. Home, in response to MakeUnique, is permitted to use SnpMakeInvalid only when either the Request TagOp value is *Update* or the Home knows that the Snoopee does not have Dirty tags.

The only permitted TagOp value in response to MakeUnique is *Invalid*.

Cache Maintenance Operations must operate on both the data and the corresponding memory tags. A MakeInvalid that permits dropping of Dirty data without writing to memory must write Dirty tags to memory.

12.7 Atomic transactions

TagOp is applicable in Atomic transactions. The permitted values for the field are *Invalid* and *Match*.

The Physical Tags to be matched are provided in the write data and correspond to the valid data bytes in AtomicLoad, AtomicStore, and AtomicSwap. Only one set of tag bits are applicable in these Atomic transactions because the maximum data size is 8-byte. The remaining tag bits in the set are not applicable and must be set to zero.

In AtomicCompare with a data size of up to 16 byte the valid data still corresponds to only one set of tag bits.

In AtomicCompare with data size of 32-byte the individual compare and swap data is only 16-byte. Only one set of Physical Tag bits is required to be matched when TagOp is set to *Match*. Physical Tags must be duplicated to cover both Compare and Swap data. The Completer is permitted to use either set of Physical Tags to perform Tag Match.

The permitted TagOp values in the CompData response to Non-store Atomic transactions are *Invalid* and *Transfer*.

The Write data for Atomic transactions where TagOp is *Invalid* must have all TU bits and all the Tag bits set to zero.

12.8 Stash transactions

In StashOnce and StashOnceSep transactions, TagOp values of *Invalid* and *Transfer* are permitted.

For Stash snoop interaction with Memory Tagging see [Stash snoops on page 12-392](#).

12.9 Snoop requests

This section describes the permitted use by Home of the following snoop types:

- [Non-forwarding snoops](#)
- [Forwarding snoops](#)
- [Stash snoops on page 12-392](#)

12.9.1 Non-forwarding snoops

Home can use any applicable Non-forwarding snoop when tags are needed by the request. If the Snoop response returns data to Home but not tags, the Home is responsible for obtaining tags before returning the Data response to the Requester.

A Home in response to WriteUniqueFull, WriteUniqueFullStash, MakeUnique, and MakeInvalid must not use the SnpMakeInvalid snoop request unless either:

- The transaction is WriteUniqueFull, WriteUniqueFullStash, or MakeUnique with a TagOp value of *Update*.
- The Home can determine that the Snoopee does not hold Dirty tags.

———— **Note** ————

By sending a ReadUnique with TagOp *Fetch*, a Requester is indicating its willingness to update the full cache line but not the tags. Home must not use SnpMakeInvalid in response to such a request, to avoid losing modified tags at the Snoopee.

12.9.2 Forwarding snoops

The use by Home of the Forwarding snoop is permitted only if the request does not need to fetch tags. A Forwarding snoop is permitted to be sent even when the Snoopee has Valid tags. If the Snoopee has Dirty tags, when responding to a Forwarding snoop, it must not forward Dirty tags to the Requester nor split dirtiness or uniqueness of tags and data.

A Snoopee is always permitted to forward Clean tags to the Requester.

When tags are Clean, the Snoopee must follow the same data transfer rules as in the Non-MTE case.

When tags are Dirty the Snoopee must follow the rules:

- For the invalidating Forwarding snoop SnpUniqueFwd and SnpPreferUniqueFwd handled as an invalidating snoop:
 - Must not forward data to the Requester.
 - Must return data and tags to the Home.
 - For the Non-invalidating Forwarding snoops SnpCleanFwd, SnpSharedFwd, SnpNotSharedDirtyFwd SnpPreferUniqueFwd handled as a non-invalidating snoop:
 - Must treat the snoop as SnpCleanFwd.
- #### ———— **Note** ————
- Same as SnpNotSharedDirtyFwd.
- For SnpOnceFwd:
 - Permitted to return Dirty tags to the Home.
 - Dirty tags must be kept at the Snoopee if the data transfer to Home is not performed.
 - Dirty tags must be written back to Home if the cache line is being invalidated or Dirty data is being written back to Home.

A Snoopee is permitted, but not required, to convert any Forwarding snoop to its corresponding Non-forwarding snoop.

Note

This property is similar to that in the Non-MTE case.

See [Permitted TagOp values in Snoop responses](#) for more details.

12.9.3 Stash snoops

Because the SNP channel does not include a TagOp field, the Home cannot forward the Requester's TagOp intentions to the Stash target.

The permitted TagOp values in Snoop responses are:

- *Invalid* in response to SnpStash*.
- *Invalid*, *Transfer*, and *Update* in response to SnpUniqueStash.
- *Invalid* in response to SnpMakeInvalidStash.

See [Permitted TagOp values in Snoop responses](#) for more details.

The requirements for determining the TagOp value in the Read request implied from the Data Pull request in the Snoop response are as follows:

For a Data Pull request in response to SnpStash*:

- If the TagOp value in the original request is *Transfer*, then it is recommended that Clean tags are returned in response to the Data Pull request.
- If the TagOp value in the original request is *Invalid*, then it is recommended that Clean tags are returned in response to the Data Pull request if tags are available.

For a Data Pull request in response to SnpUniqueStash:

- Irrespective of the presence or absence of data in the Snoop response and for any cache state, it is recommended that, if tags are available when data is returned, Clean tags are returned in response to a Data Pull request.

12.9.4 Permitted TagOp values in Snoop responses

The permitted tag field values in Snoop responses are:

- For SnpResp, the TagOp field is inapplicable and must be set to zero.
- For SnpRespDataPtl, the permitted TagOp value is *Invalid*. Both the TU and the Tag field must be set to zero and ignored by the receiver.
- For SnpRespData:
 - *Invalid*. All Tag fields must be set to zero.
 - *Transfer*. Clean tags must be returned. TU bits are inapplicable and must be set to zero.
 - *Update*. All TU bits must be asserted. The data state must include Pass Dirty.
 - *Match*. Not permitted.

12.10 Home to Subordinate transactions

For a Read request to the Subordinate:

- The permitted TagOp values are *Invalid*, *Transfer*, and *Fetch*.

For a Write request to the Subordinate:

- The permitted TagOp values are *Invalid*, *Transfer*, *Update*, and *Match*.

For an Atomic request to the Subordinate:

- The permitted TagOp values are *Invalid*, and *Match*.

A ReadNoSnp or ReadNoSnpSep with TagOp *Transfer* or *Fetch* can be used to fetch tags from the Subordinate. Tags can be returned from a Subordinate to the Home directly or sent to the Requester using DMT. When TagOp *Fetch* is used then the Subordinate is not required to return valid data. TagOp *Fetch* is permitted only with a data size of 64 bytes.

When memory needs to be updated with tags, WriteNoSnp with TagOp *Update* must be used. When only tags need to be updated, the data byte enables can be set to all zero.

When TagOp is *Match*, the TagGroupID in WriteNoSnp and Atomic transactions to the Subordinate are applicable, and these values must be returned in the TagMatch response.

When Atomic operations are performed at the Subordinate Node, the Home is permitted to include TagOp *Match* in Atomic requests to the Subordinate. Where the tag match is performed at the Subordinate, in both non-Store Atomic and Store Atomic transactions, the TagMatch response TgtID must be obtained from the ReturnNID value in the request. To support this feature, it is required that the ReturnNID in the Atomic Store from a Home Node to a Subordinate Node is applicable and must be set to the same value as the SrcID in the request.

Note

Applicability of the ReturnNID in non-Store Atomic transactions is already a requirement in the previous version of this specification.

12.11 Error response

The following sub-sections describe Error response handling for:

- [Tag Match](#)
- [Non-Tag Match errors](#)
- [MTE not supported on page 12-395](#)

12.11.1 Tag Match

Write and Atomic transactions that have TagOp value of *Match* must return the results of the Tag Match operation. The results are returned using the TagMatch message. The transaction must proceed as normal irrespective of the Tag Match result. The TagMatch response must be sent even if the WriteData is canceled or a Tag Match is not performed.

———— Note ————

Using a separate TagMatch message adds complexity and extra messages to the Write and Atomic transactions but has the advantage that it provides a sufficiently accurate response mechanism. Using a separate response does not delay the sending of the Comp response.

The TagMatch message characteristics are:

- It is sent by the Completer performing the Tag Match operation. This can be a Home Node or a Subordinate Node.
- The TgtID value in the message is copied from:
 - SrcID in the request if the Completer is a Home Node.
 - ReturnNID in the request if the Completer is a Subordinate Node. The ReturnNID can point to the Requester or the Home. When the Subordinate returns the TagMatch response to the Home, if required by the transaction, the Home is responsible for forwarding the response to the Requester.
- The response must return the TagGroupID value from the request.
- The TraceTag field is inapplicable and can take any value.
- The Resp field value in the response indicates the Tag Match state as either pass or fail. See [Response status, Resp on page 13-444](#).
- The TagMatch response can be sent as soon as the Completer can determine the result. TagMatch is permitted to be sent without waiting for data. This can occur when the Completer does not support MTE.
- The Resp value in the TagMatch response must be:
 - A Fail when MTE is not supported.
 - A Pass when MTE is supported but the Tag Match is not performed. For example, when an Exclusive write fails and the Tag Match is not performed.
 - Accurate, if the match is performed.

12.11.2 Non-Tag Match errors

Permitted Data and Non-data error responses to requests are independent of the presence or absence of Memory Tagging.

Permitted RespErr field values in the TagMatch response are OK, DERR, and NDERR. See [Error response use by transaction type on page 9-345](#).

When the RespErr field in a response is NDERR then:

- The TagOp in the response to the Requester is inapplicable and can take any value.
- The Snoop response must be Invalid.

Poison on tags is not supported. See [Poison on page 9-355](#).

12.11.3 MTE not supported

When a Completer does not support MTE for the address in the request, the Completer must send a TagOp value of *Invalid* in response to a Read transaction with a TagOp value of *Transfer* or *Fetch*. The returned tags must be set to zero. The returned tags can be cached as Clean by the Requester.

A Completer in response to a Read request to a Non-cacheable or Device memory location must set the TagOp value in the response to *Invalid*. A Completer is expected to give an OK response on RespErr to an MTE operation, unless it would have given a different response to an equivalent non-MTE operation.

When a Write request with TagOp *Match* is received and a Completer does not support MTE for the address in the request, the Completer is still required to send a TagMatch response. The Resp field value must indicate that the Tag Match failed. The Completer is permitted, but not required, to wait for the write data before sending the TagMatch response.

12.12 Requests and permitted tag operations

Table 12-3 shows a summary of the permitted TagOp field values in the different requests. The following key is used:

Y	Yes, permitted
N	No, not permitted

Table 12-3 Permitted TagOp values for each request type

Requests	Tag operation				
	Invalid	Transfer	Update	Match	Fetch
ReadOnce	Y	Y	N	N	N
ReadClean					
ReadShared					
ReadNotSharedDirty					
ReadPreferUnique					
ReadUnique	Y	Y	N	N	Y
ReadNoSnp	Y	Y	N	N	Y
ReadNoSnpSep					
ReadOnce*Invalid	Y	N	N	N	N
MakeReadUnique	Y	Y	N	N	N
CleanShared	Y	N	N	N	N
CleanSharedPersist					
CleanSharedPersistSep					
CleanUnique	Y	N	N	N	N
CleanInvalid					
MakeInvalid					
MakeUnique	Y	N	Y	N	N
Evict	Y	N	N	N	N
StashOnceUnique	Y	Y	N	N	N
StashOnceSepUnique					
StashOnceShared					
StashOnceSepShared					
WriteNoSnpFull	Y	Y	Y	Y	N
WriteUniqueFull	Y	N	Y	Y	N
WriteUniqueFullStash					
WriteNoSnpPtl	Y	N	Y	Y	N
WriteUniquePtl					
WriteUniquePtlStash					
WriteBackFull	Y	Y	Y	N	N
WriteCleanFull					
WriteBackPtl	Y	N	N	N	N

Table 12-3 Permitted TagOp values for each request type (continued)

Requests	Tag operation				
	Invalid	Transfer	Update	Match	Fetch
WriteEvictFull WriteEvictOrEvict	Y	Y	N	N	N
WriteNoSnPFull+(P)CMO	Y	Y	Y	N	N
WriteNoSnPPtl+(P)CMO	Y	N	Y	N	N
WriteUniqueFull+(P)CMO	Y	N	N	N	N
WriteUniquePtl+(P)CMO	Y	N	N	N	N
WriteBackFull+(P)CMO	Y	Y	Y	N	N
WriteCleanFull+(P)CMO	Y	Y	Y	N	N
WriteNoSnPZero	Y	N	N	N	N
WriteUniqueZero	Y	N	N	N	N
Atomic*	Y	N	N	Y	N
PrefetchTgt	Y	Y	N	N	N
PCrdReturn DVMOp	Y	N	N	N	N

The TagOp field in ReqLCrdReturn, DatLCrdReturn, and RspLCrdReturn is inapplicable and can take any value.

The Tag and TU fields in DatLCrdReturn are inapplicable and can take any value.

12.13 TagOp field use summary

The following sections give a summary of the use of the TagOp field in messages in different channels:

REQ channel message:

- Read* and MakeReadUnique transaction:
 - TagOp field can be *Invalid*, *Transfer*, or *Fetch*.
 - TagOp *Fetch* is permitted only in ReadUnique, ReadNoSnp, and ReadNoSnpSep transactions.
 - TagOp field *Transfer* indicates whether Allocation Tags must be returned alongside read data.
 - TagOp field *Fetch* indicates only valid tags are required to be returned. Returned data is not required to be valid.
- Write transaction:
 - TagOp field can be *Invalid*, *Transfer*, *Match* or *Update*.
 - TagOp field *Transfer* indicates Clean tags are being transferred and tags can be cached alongside the data.
 - TagOp field *Match* indicates a Match check is required between the Physical Tags in the message and the Allocation Tags at the memory location.
 - TagOp field *Update* indicates Dirty tags are being passed, which must update the Allocation Tag values.
- MakeUnique transaction:
 - TagOp field can be *Invalid* or *Update*.
 - TagOp field *Update* indicates all tags will be written to.
- Atomic transaction:
 - TagOp field can be *Invalid* or *Match*.
 - TagOp field *Match* indicates whether a Tag Match is required.
- StashOnce transaction:
 - TagOp field can be: *Invalid* or *Transfer*.
 - TagOp field *Transfer* indicates whether Allocation Tags should be stashed alongside Stash data.
- PrefetchTgt transaction:
 - TagOp value can be *Invalid* or *Transfer*.
- For all the other REQ channel messages, the TagOp field is inapplicable and must be zero.

DAT channel message:

- For Read data, the TagOp field indicates whether the Allocation Tags sent along with the data are Invalid, Clean, or Dirty.
- For Snoop data, the TagOp field indicates whether the Allocation Tags sent in the Snoop response are Invalid, Clean, or Dirty.
- For write data, the TagOp field indicates whether the Allocation Tags sent in the write data are Invalid, Clean, Dirty, or a Match check is required. The TagOp value must be the same as in the Request message except when a snoop has downgraded the state of the tags or the write has been canceled.

RSP channel message:

- For a Comp response, the TagOp field is only used in response to a MakeReadUnique transaction and is used to indicate if responsibility for Dirty tags is being passed to the Requester.
- For all other RSP channel messages, the TagOp field is inapplicable and must be zero.

SNP message:

- The TagOp field is not present in the SNP channel.

Chapter 13

Link Layer

This chapter describes the Link layer that provides a streamlined mechanism for packet-based communication between nodes and the interconnect across links. It contains the following sections:

- [Introduction on page 13-402](#)
- [Link on page 13-403](#)
- [Flit on page 13-404](#)
- [Channel on page 13-405](#)
- [Port on page 13-407](#)
- [Node interface definitions on page 13-408](#)
- [Increasing inter-port bandwidth on page 13-410](#)
- [Channel interface signals on page 13-414](#)
- [Flit packet definitions on page 13-418](#)
- [Protocol flit fields on page 13-424](#)
- [Link flit on page 13-450](#)

13.1 Introduction

The Link layer provides a streamlined mechanism for packet-based communication between nodes and the interconnect.

The Link layer defines packet and flit formats and flow control across a link.

Figure 13-1 shows a typical system using link-based communication.

Figure 13-1 System using link based communication

Interface parity signals, which are discussed in [Use of interface parity on page 9-357](#), are not included in this chapter.

13.2 Link

Flit communication occurs between a Transmitter and a Receiver pair.

The connection between a Transmitter and a Receiver is referred to as a link.

Two-way communication between a node and the interconnect requires a pair of links. [Figure 13-2](#) shows the link requirements.

Figure 13-2 Two-way link communication

13.2.1 Outbound and inbound links

The link used by a Transmitter to send packets is defined as the outbound link.

The link used by a Receiver to receive packets is defined as the inbound link.

[Figure 13-3](#) shows the outbound and inbound links at a node. The interface at the interconnect has a complementary pair of links.

Figure 13-3 Outbound and inbound links

13.3 Flit

A flit is the basic unit of transfer in the Link layer.

Packets are formatted into flits and transmitted across a link. There are two types of flits:

Protocol flit A Protocol flit carries a protocol packet in its payload. In this specification, every protocol packet is mapped into exactly one protocol flit.

Link flit A Link flit carries messages associated with link maintenance. For example, a Transmitter uses a Link flit to return a Link layer Credit, also referred to as an L-Credit, to the Receiver during a link deactivation sequence.

Link flits originate at a link Transmitter and terminate at the link Receiver connected at the other side of the link.

13.4 Channel

In this specification, the Link layer provides a set of channels for flit communication.

Each channel has a defined flit format that has multiple fields and some of the field widths have multiple possible values. In some cases, the defined flit format can be used on both an inbound and an outbound channel.

Table 13-1 shows the channels, and the mapping onto the Request Node and Subordinate Node component channels.

Table 13-1 Channels' mapping onto the RN and SN component channels

Channel	Description	Usage	RN Channel	SN Channel
REQ Request	The request channel transfers flits associated with request messages such as Read requests and Write requests. See Request, REQ, channel on page 13-414 .	All Requests	TXREQ	RXREQ
RSP Response	The response channel transfers flits associated with response messages that do not have a data payload such as write completion messages. See Response, RSP, channel on page 13-415 .	Responses from the Completer	RXRSP	TXRSP
		Snoop Response and Completion Acknowledge	TXRSP	-
SNP Snoop	The snoop channel transfers flits associated with Snoop and SnpDVMOp Request messages. See Snoop, SNP, channel on page 13-416 .	All Snoop requests	RXSNP	-
DAT Data	The data channel transfers flits associated with protocol messages that have a data payload such as read completion and WriteData messages. See Data, DAT, channel on page 13-417 .	WriteData, and Snoop response data from an RN	TXDAT	RXDAT
		Read data	RXDAT	TXDAT

13.4.1 Channel dependencies

The following dependencies are permitted between the channels in the protocol.

For a Request Node:

- Must make forward progress on the inbound SNP channel without requiring forward progress on outbound REQ channel.
- Permitted, but not required, to wait for forward progress on the outbound RSP channel before making forward progress on the inbound SNP channel.
- Permitted, but not required, to wait for forward progress on the outbound DAT channel before making forward progress on the inbound SNP channel.
- Must make forward progress on the inbound RSP channel without requiring forward progress on any other channel.
- Must make forward progress on the inbound DAT channel without requiring forward progress on any other channel.

———— **Note** ————

The requirement that a Request Node must make forward progress on the inbound RSP and DAT channel, without requiring forward progress on any other channel, means that a Request Node must be able to accept all Comp and CompData responses for outstanding transactions without sending any CompAck responses.

For a Subordinate Node:

- Permitted, but not required, to wait for forward progress on the outbound RSP channel before making forward progress on the inbound REQ channel.
- Must make forward progress on the inbound REQ channel without requiring forward progress on the outbound DAT channel.
- Must make forward progress on the inbound DAT channel without requiring forward progress on any other channel.

13.5 Port

A Port is defined as the set of all links at the interface of a node.

Figure 13-4 shows the relationship between links, channels, and port. See [Node interface definitions on page 13-408](#) for the specific node requirements, See [Channel interface signals on page 13-414](#), and [Chapter 14 Link Handshake](#) for signal details.

Figure 13-4 Relationship between links, channels, and port

13.6 Node interface definitions

The nodes exchange messages by sending flits across the node interface. This section describes two node types of node interfaces supported in this specification:

- [Request Nodes](#)
- [Subordinate Nodes](#) on page 13-409

———— Note ————

The **LINKACTIVE** interface pins and signals used by each node for link management are described in [Chapter 14 Link Handshake](#).

13.6.1 Request Nodes

This section describes the Request Node interfaces:

- [RN-F](#)
- [RN-D](#)
- [RN-I](#) on page 13-409

RN-F

The RN-F interface uses all channels and is used by a fully coherent Requester such as a core or cluster. [Figure 13-5](#) shows the RN-F interface.

Figure 13-5 RN-F interface

RN-D

The RN-D interface uses all channels and is used by an IO coherent node that processes DVM messages. Use of the SNP channel is limited to DVM transactions. See [DVM transaction flow](#) on page 8-314 for details. [Figure 13-6](#) shows the RN-D interface.

Figure 13-6 RN-D interface

RN-I

The RN-I interface uses all channels, with the exception of the SNP channel, and is used by an IO coherent Request Node such as a GPU or IO bridge. A SNP channel is not required because an RN-I node does not include a hardware-coherent cache or TLB. [Figure 13-7](#) shows the RN-I interface.

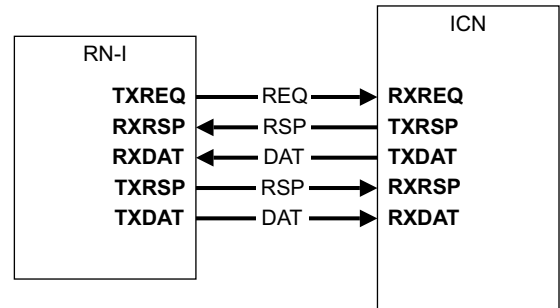

Figure 13-7 RN-I interface

13.6.2 Subordinate Nodes

This section describes the Subordinate Node interfaces, SN-F and SN-I.

SN-F and SN-I

The SN-F and SN-I interfaces are identical and use a RX request channel, a TX response channel, a TX data channel, and an RX data channel. The SN-F and SN-I receive request messages from the interconnect and return response messages to the interconnect. However, the SN-F and SN-I receive different types of transactions. [Figure 13-8](#) shows the SN-F and SN-I interface.

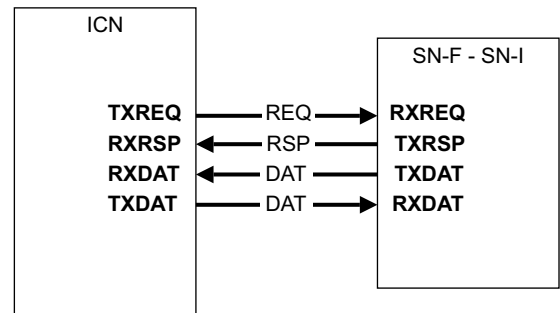

Figure 13-8 SN-F and SN-I interface

13.7 Increasing inter-port bandwidth

The available bandwidth at a node interface can be increased in several ways. Two architectural methods permitted are detailed in the following sections:

- [Multiple interfaces](#)
- [Replicated channels on a single interface on page 13-412](#)

13.7.1 Multiple interfaces

The simplest method for a component to increase the available bandwidth is to have multiple interfaces. A complete interface can be duplicated. The number of times an interface on a node is duplicated is IMPLEMENTATION DEFINED.

Figure 13-9 shows an example of duplicated interfaces.

Figure 13-9 Multiple interface example

The main features of this method of increasing bandwidth across two interfaces are:

- Each interface has its own:
 - NodeID
 - TxnID pool
 - Set of **SACTIVE** signals
 - Set of **LINKACTIVE** signals
 - Set of **SYSCOREQ/SYSCOACK** signals
 - Set of optional broadcast control pins
- Each duplicate interface must be treated as an independent interface:
 - If one interface allocates the cache line, another duplicate interface cannot deallocate that cache line.
 - When responding to a request, the Completer must send the response on the same interface as the one used by the request.
 - A snoop must be sent to the same interface that was used for the transaction that caused the allocation of a cache line.
 - A transaction from one interface must make forward progress without requiring forward progress of a transaction on a duplicate interface.
- All channels must be replicated even when only a subset of the channels needs increased bandwidth.

Address striping

This specification permits an optional optimization where a Request Node can specify the address striping that it will use to select between multiple interfaces. This can be specified for any number of interfaces.

A Request Node is permitted to use address striping to guide its requests to the appropriate interface without declaring the striping algorithm being used.

A Home Node typically can filter snoops based on a snoop filter. If the snoop filter is precise, it can track the Node ID of the Requester that cached the cache line and send a snoop for a subsequent request to the same cache line on a single interface. A snoop filter that does not track precisely or is sized to the number of components in the system instead of the number of Request Node interfaces will not be able to isolate the single interface it needs to send the snoop on, unless the snoop filter knows and uses the same address striping algorithm as the Requester.

When a Request Node does not declare the striping algorithm it is using, the snoop filters either need to be larger or the Home will have to send redundant snoops. It is recommended that a Request Node that uses address striping advertises the striping algorithm so that the Home Nodes can make use of it.

The address striping used by a Request Node can be specified by a hash function.

Hash function example

This section describes a suggested hash function to be used to distribute requests across multiple REQ interfaces. The same hash function can be used to distribute snoops across multiple available SNP interfaces. The steps in generating the interface number are:

1. The cache line aligned input address is first filtered through a predefined Hash Mask. The most significant address bits that are not used must be set to all zero before filtering the address. In this example, the result of the filtering is Mask_Result.
2. The individual bits of Mask_Result are XORed to obtain the target interface.

Where the number of interfaces is a power-of-two:

- For 2 interfaces:

$$\text{Interfaces}[0] = \text{Mask_Result}[n-1] \wedge \text{Mask_Result}[n-2] \dots \text{Mask_Result}[7] \wedge \text{Mask_Result}[6]$$
- For 4 interfaces:

$$\text{Interfaces}[1:0] = \text{Mask_Result}[n-1:n-2] \wedge \text{Mask_Result}[n-3:n-4] \dots \text{Mask_Result}[9:8] \wedge \text{Mask_Result}[7:6]$$
- For 8 interfaces:

$$\text{Interfaces}[2:0] = \text{Mask_Result}[n-1:n-3] \wedge \text{Mask_Result}[n-4:n-6] \dots \text{Mask_Result}[11:9] \wedge \text{Mask_Result}[8:6]$$

This example does not cover the situation where the number of interfaces is not a power-of-two.

13.7.2 Replicated channels on a single interface

Rather than replicating a complete interface through more complex methods, a more efficient method to increase the available interface bandwidth is to selectively replicate the channels that require greater bandwidth.

Figure 13-10 shows an example of replicated channels.

Figure 13-10 Replicated channels example

Features

The main features of this method of increasing available bandwidth are described in this section.

Each channel can be selectively replicated. There are no restrictions on which channels are replicated. Typically, replication of a channel is based on the expected bandwidth required on that channel. For example, in Figure 13-10, TXREQ is duplicated as TXREQ0, TXREQ1, whereas RXSNP is not duplicated and has only RXSNP0. The characteristics of the replicated channel interface are:

- All replicated DAT subchannels corresponding to a single DAT channel must be of the same width.
- The complete interface must use:
 - The same NodeID
 - A single TxnID pool
- Messages within a transaction can use any subchannel:
 - A response message does not need to use the same subchannel as the request. For example, Request on TXREQ0 can give a response on either RXRSP0 or RXRSP1.
 - Multiple response messages for a single request can come on any subchannel. For example, DBIDResp for a write transaction is received on RXRSP0 whereas the corresponding Comp can be received on RXRSP1.
- Like non-replicated channels, replicated channels do not provide any in-channel ordering guarantees.
- All link crediting is done on a subchannel basis.
 - Cannot use the credit for TXREQ0 to send the flit on TXREQ1.
 - Credits are required to be provided by the Receiver on all subchannels.
- Protocol credits are for the combined TXREQ channel.
- There is no support for powering down a subchannel individually.
- The two parts of a DVM snoop can come on either subchannel. Each part can be on a different subchannels.
- The number of subchannels on two connected interfaces must match.

- There must be only one set of **SACTIVE**, **LINKACTIVE**, and **SYSCOREQ/SYSCOACK** signals, and optional broadcast control pins.
- Interface property `CCF_Wrap_Order` is not permitted to be set to `True` when the interface includes replicated DAT channels.

Note

When a channel has been replicated on an interface, it is IMPLEMENTATION DEFINED which of the subchannels is used for a transfer.

13.8 Channel interface signals

This section describes the channel interfaces. It contains the following sections:

- [Request, REQ, channel](#)
- [Response, RSP, channel](#) on page 13-415
- [Snoop, SNP, channel](#) on page 13-416
- [Data, DAT, channel](#) on page 13-417

13.8.1 Request, REQ, channel

[Figure 13-11](#) shows the REQ channel interface pins, where R is the width of REQFLIT.

Figure 13-11 REQ channel interface pins

[Table 13-2](#) shows the REQ channel interface signals.

Table 13-2 REQ channel interface signals

Signal	Description
REQFLITPEND	Request Flit Pending. Early indication that a request flit might be transmitted in the following cycle. See Flit level clock gating on page 14-455.
REQFLITV	Request Flit Valid. The transmitter sets this signal HIGH to indicate when REQFLIT[(R-1):0] is valid.
REQFLIT[(R-1):0]	Request Flit. See Request flit on page 13-418 for a description of the request flit format.
REQLCRDV	Request L-Credit Valid. The receiver sets this signal HIGH to return a request channel L-Credit to a transmitter. See L-Credit flow control on page 14-453.

13.8.2 Response, RSP, channel

Figure 13-12 shows the RSP channel interface pins, where T is the width of **RSPFLIT**. The same interface is used for both inbound and outbound RSP channels.

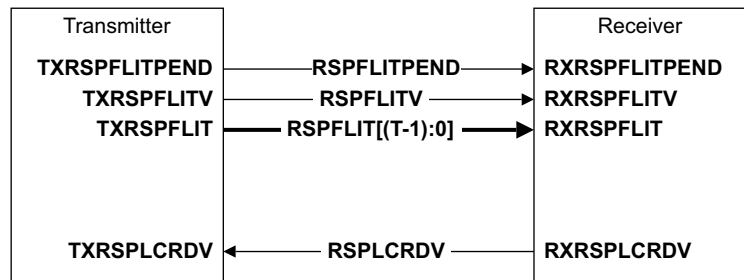

Figure 13-12 RSP channel interface pins

Table 13-3 shows the RSP channel interface signals.

Table 13-3 RSP channel interface signals

Signal	Description
RSPFLITPEND	Response Flit Pending. Early indication that a response flit might be transmitted in the following cycle. See <i>Flit level clock gating</i> on page 14-455.
RSPFLITV	Response Flit Valid. The transmitter sets this signal HIGH to indicate when RSPFLIT[(T-1):0] is valid.
RSPFLIT[(T-1):0]	Response Flit. See <i>Response flit</i> on page 13-420 for a description of the response flit format.
RSPLCRDV	Response L-Credit Valid. The receiver sets this signal HIGH to return a response channel L-Credit to a transmitter. See <i>L-Credit flow control</i> on page 14-453.

13.8.3 Snoop, SNP, channel

Figure 13-13 shows the SNP channel interface pins, where S is the width of **SNPFLIT**.

Figure 13-13 SNP channel interface pins

Table 13-4 shows the SNP channel interface signals.

Table 13-4 SNP channel interface signals

Signal	Description
SNPFLITPEND	Snoop Flit Pending. Early indication that a snoop flit might be transmitted in the following cycle. See <i>Flit level clock gating</i> on page 14-455.
SNPFLITV	Snoop Flit Valid. The transmitter sets this signal HIGH to indicate when SNPFLIT[(S-1):0] is valid.
SNPFLIT[(S-1):0]	Snoop Flit. See <i>Snoop flit</i> on page 13-421 for a description of the snoop flit format.
SNPLCRDV	Snoop L-Credit Valid. The receiver sets this signal HIGH to return a snoop channel L-Credit to a transmitter. See <i>L-Credit flow control</i> on page 14-453.

13.8.4 Data, DAT, channel

Figure 13-14 shows the DAT channel interface pins, where D is the width of **DATFLIT**. The same interface is used for both inbound and outbound DAT channels.

Figure 13-14 DAT channel interface pins

Table 13-5 shows the DAT channel interface signals.

Table 13-5 DAT channel interface signals

Signal	Description
DATFLITPEND	Data Flit Pending. Early indication that a data flit might be transmitted in the following cycle. See Flit level clock gating on page 14-455 .
DATFLITV	Data Flit Valid. The transmitter sets this signal HIGH to indicate when DATFLIT[(D-1):0] is valid.
DATFLIT[(D-1):0]	Data Flit. See Data flit on page 13-422 for a description of the data flit format.
DATLCRDV	Data L-Credit Valid. The receiver sets this signal HIGH to return a data channel L-Credit to a transmitter. See L-Credit flow control on page 14-453 .

13.9 Flit packet definitions

This section defines the flit format. See:

- [Request flit](#)
- [Response flit](#) on page 13-420
- [Snoop flit](#) on page 13-421
- [Data flit](#) on page 13-422

13.9.1 Request flit

Table 13-6 shows the Request flit format in a REQ channel packet starting at bit zero. The following key is used:

SBZ Should Be Zero

Table 13-6 Request flit format

REQFLIT[(R-1):0] format		
Field	Field width	Comments
QoS	4	-
TgtID	7 to 11	Width determined by NodeID_Width
SrcID	7 to 11	Width determined by NodeID_Width
TxnID	12	-
ReturnNID	7 to 11	Used for DMT
StashNID		Used in Stash transactions
{(NodeID_Width - 7)'b0,		SBZ
SLCRepHint[6:0]}		Used in cache line replacement algorithms
StashNIDValid	1	Used in Stash transactions
Endian		Used in Atomic transactions
Deep		Used in CleanSharedPersist* transactions
ReturnTxnID[11:0]	12	Used for DMT
{6'b0,		SBZ
StashLPIDValid,		Used in Stash transactions
StashLPID[4:0]}		Used in Stash transactions
Opcode	7	-
Size	3	-
Addr	RAW = 44 to 52	Width determined by Req_Addr_Width (RAW)
NS	1	-
LikelyShared	1	-
AllowRetry	1	-
Order	2	-
PCrdType	4	-
MemAttr	4	-

Table 13-6 Request flit format (continued)

REQFLIT[(R-1):0] format		
Field	Field width	Comments
SnpAttr DoDWT	1	- Used for DWT
{3'b0, LPID[4:0]} PGroupID[7:0] StashGroupID[7:0] TagGroupID[7:0]	8	SBZ - Used in Persistent CMO transactions Used in the StashOnceSep transaction Used for Memory Tagging
Excl SnoopMe	1	Used in Exclusive transactions Used in Atomic transactions
ExpCompAck	1	-
TagOp	2	-
TraceTag	1	-
MPAM	M = 0	No MPAM bus
	M = 11	-
RSVDC	Y = 0	No RSVDC bus
	Y = 4, 8, 12, 16, 24, 32	-
Total	R = (87 + RAW + M + Y) to (99 + RAW + M + Y)	

13.9.2 Response flit

Table 13-7 shows the Response flit format in a RSP channel packet starting at bit zero,

Table 13-7 Response flit format

RSPFLIT[(T-1):0] format		
Field	Field width	Comments
QoS	4	-
TgtID	7 to 11	Width determined by NodeID_Width
SrcID	7 to 11	Width determined by NodeID_Width
TxnID	12	-
Opcode	5	-
RespErr	2	-
Resp	3	-
FwdState[2:0]	3	Used for DCT
DataPull[2:0]		Used in Stash transactions
CBusy	3	-
DBID[11:0]	12	-
{4'b0, PGroupID[7:0]}		SBZ Used in Persistent CMO transactions
{4'b0, StashGroupID[7:0]}		SBZ Used in Stash transactions
{4'b0, TagGroupID[7:0]}		SBZ Used for Memory Tagging
PCrdType	4	-
TagOp	2	-
TraceTag	1	-
Total	T = 65 to 73	-

13.9.3 Snoop flit

Table 13-8 shows the Snoop flit format in a SNP channel packet starting at bit zero.

Table 13-8 Snoop flit format

SNPFLIT[(S-1):0] format		
Field	Field width	Comments
QoS	4	-
SrcID	7 to 11	Width determined by NodeID_Width
TxnID	12	-
FwdNID	7 to 11	Width determined by NodeID_Width
FwdTxnID[11:0] {6'b0, StashLPIDValid, StashLPID[4:0]} {4'b0, VMIDExt[7:0]}	12	Used for DCT SBZ Used in Stash transactions Used in Stash transactions SBZ Used in DVM transactions
Opcode	5	-
Addr	SAW = 41 to 49	Req_Addr_Width - 3
NS	1	-
DoNotGoToSD	1	-
RetToSrc	1	-
TraceTag	1	-
MPAM	M = 0	No MPAM bus
	M = 11	-
Total	S = 51 + SAW + M to 59 + SAW+ M	-

13.9.4 Data flit

Table 13-9 shows the Data flit format in a DAT channel packet starting at bit zero.

The number of data flits required is dependent on the number of data bytes, and the data bus width. See [Data packetization on page 2-144](#).

The data channel interface supports a 128-bit, 256-bit, and 512-bit data bus width. There are three data flit formats defined, one for each of the three data bus widths supported at the data channel interface.

DataCheck (DC) field width is either zero or equal to the width of the Data field divided by 8.

Poison (P) field width is either zero or equal to the width of the Data field divided by 64.

Table 13-9 Data flit fields

DATFLIT[D-1:0] format		
Field	Field Width	Comments
QoS	4	-
TgtID	7 to 11	Width determined by NodeID_Width
SrcID	7 to 11	Width determined by NodeID_Width
TxnID	12	-
HomeNID	7 to 11	Width determined by NodeID_Width
Opcode	4	-
RespErr	2	-
Resp	3	-
{1'b0, FwdState[2:0]}	4	SBZ Used for DCT
{1'b0, DataPull[2:0]}		SBZ
DataSource[3:0]		Used in Stash transactions Indicates Data source in a response
CBusy	3	-
DBID[11:0]	12	-
CCID	2	-
DataID	2	-
TagOp	2	-
Tag	DW/32 = 4, 8, 16	-
TU	DW/128 = 1, 2, 4	-
TraceTag	1	-
RSVDC	Y = 0	No RSVDC bus
	Y = 4, 8, 12, 16, 24, 32	-
BE	DW/8 = 16, 32, 64	-
Data	DW = 128, 256, 512	DW = Data bus width

Table 13-9 Data flit fields (continued)

DATFLIT[D-1:0] format		
Field	Field Width	Comments
DataCheck (DC)	0 or DW/8 = 16, 32, 64	-
Poison (P)	0 or DW/64 = 2, 4, 8	-
Total	$D = (221 \text{ to } 233) + Y + DC + P$	DW = 128 bit Data
	$D = (370 \text{ to } 382) + Y + DC + P$	DW = 256 bit Data
	$D = (668 \text{ to } 680) + Y + DC + P$	DW = 512 bit Data

13.10 Protocol flit fields

A Protocol flit is identified by a non-zero value in the opcode field. All the flit fields defined in this section are applicable for a Protocol flit. The following sections describe the encoding of the Protocol flit fields:

- [Quality of Service, QoS](#) on page 13-425
- [Target Identifier, TgtID](#) on page 13-425
- [Source Identifier, SrcID](#) on page 13-425
- [Home Node Identifier, HomeNID](#) on page 13-425
- [Return Node Identifier, ReturnNID](#) on page 13-425
- [Forward Node Identifier, FwdNID](#) on page 13-425
- [Logical Processor Identifier, LPID](#) on page 13-426
- [Persistence Group Identifier, PGroupID](#) on page 13-426
- [Stash Node Identifier, StashNID](#) on page 13-426
- [Stash Node Identifier Valid, StashNIDValid](#) on page 13-427
- [Stash Logical Processor Identifier, StashLPID](#) on page 13-427
- [Stash Logical Processor Identifier Valid, StashLPIDValid](#) on page 13-427
- [Stash Group Identifier, StashGroupID](#) on page 13-427
- [Transaction Identifier, TxnID](#) on page 13-428
- [Return Transaction Identifier, ReturnTxnID](#) on page 13-428
- [Forwarding Transaction Identifier, FwdTxnID](#) on page 13-428
- [Data Buffer Identifier, DBID](#) on page 13-428
- [Channel opcodes, Opcode](#) on page 13-429
- [Deep persistence, Deep](#) on page 13-434
- [Address, Addr](#) on page 13-435
- [Non-secure, NS](#) on page 13-435
- [Size of transaction data, Size](#) on page 13-435
- [Memory Attribute, MemAttr](#) on page 13-437
- [Snoop Attribute, SnpAttr](#) on page 13-437
- [Do Direct Write Transfer, DoDWT](#) on page 13-438
- [Likely Shared, LikelyShared](#) on page 13-438
- [Ordering requirements, Order](#) on page 13-438
- [Exclusive, Excl](#) on page 13-440
- [Endian](#) on page 13-440
- [Allow Retry, AllowRetry](#) on page 13-440
- [Expect Completion Acknowledge, ExpCompAck](#) on page 13-441
- [SnoopMe](#) on page 13-441
- [Return to Source, RetToSrc](#) on page 13-441
- [Data Pull, DataPull](#) on page 13-441
- [Do not transition to SD state, DoNotGoToSD](#) on page 13-442
- [Protocol Credit Type, PCrdType](#) on page 13-442
- [Tag Operation, TagOp](#) on page 13-443
- [Tag](#) on page 13-443
- [Tag Update, TU](#) on page 13-443
- [Tag Group Identifier, TagGroupID](#) on page 13-443
- [Trace Tag, TraceTag](#) on page 13-444
- [Memory System Performance Resource Partitioning and Monitoring, MPAM](#) on page 13-444
- [Virtual Machine Identifier Extension, VMIDExt](#) on page 13-444
- [Response status, Resp](#) on page 13-444
- [Forward State, FwdState](#) on page 13-446
- [Completer Busy, CBusy](#) on page 13-446
- [Response Error, RespErr](#) on page 13-447

- [Data payload, Data](#) on page 13-447
- [Critical Chunk Identifier, CCID](#) on page 13-447
- [Data Identifier, DataID](#) on page 13-448
- [Byte Enable, BE](#) on page 13-448
- [Data check, DataCheck](#) on page 13-448
- [Poison](#) on page 13-448
- [Data source, DataSource](#) on page 13-449
- [System Level Caches Replacement Hint, SLCRepHint](#) on page 13-449
- [Reserved for Customer Use, RSVDC](#) on page 13-449

13.10.1 Quality of Service, QoS

This field is used to assign a Quality of Service (QoS) value to a transaction. Ascending values of QoS indicate higher priority levels. See [Chapter 10 Quality of Service](#).

13.10.2 Target Identifier, TgtID

This field is the NodeID of the component to which the message is targeted. This is used by the interconnect to determine the port to which the message is sent. See [Target Identifier, TgtID, and Source Identifier, SrcID](#) on page 2-93.

13.10.3 Source Identifier, SrcID

This field is the NodeID of the component from which the message is sent. This is used by the interconnect to determine the port from which the message has been sent. See [Target Identifier, TgtID, and Source Identifier, SrcID](#) on page 2-93.

13.10.4 Home Node Identifier, HomeNID

This field is associated with the original request. The Requester uses the value in this field to determine the TgtID of the CompAck to be sent in response to CompData. See [Home Node Identifier, HomeNID](#) on page 2-97.

Applicable in CompData and DataSepResp.

Inapplicable and must be zero in all other Data messages.

13.10.5 Return Node Identifier, ReturnNID

This field identifies the node to which the Subordinate sends a CompData, DataSepResp, or Persist response. This field also indicates the node to which the Subordinate sends DBIDResp when DoDWT = 1. The value can be either the Node ID of Home or the Requester that originated the transaction. See [Return Node Identifier, ReturnNID](#) on page 2-96.

Applicable from Home to Subordinate in ReadNoSnp, ReadNoSnpSep, CleanSharedPersistSep, WriteNoSnp, Combined Write, and Atomic requests.

Inapplicable and must be zero for all other requests. For Stash requests, the same bits in the packet are used for StashNID.

13.10.6 Forward Node Identifier, FwdNID

This field identifies the Requester to which the CompData response can be forwarded. The value must be the NodeID of the Requester that initiated the transaction. See [Forward Node Identifier, FwdNID](#) on page 2-98.

Applicable in Forward-type snoops.

Inapplicable and must be zero in all other Snoop requests, except range-based TLBI DVM operations.

In range-based TLBI DVM operations, the bits in the field are used for DVM payload.

13.10.7 Logical Processor Identifier, LPID

This field is used when a single Requester contains more than one logically separate processing agent. The SrcID is used with LPID to uniquely identify the logical processor that generated the request.

The LPID must be set to the correct value for the following transactions:

- For any Non-snoopable Non-cacheable or Device access:
 - ReadNoSnp
 - WriteNoSnp
- For Exclusive accesses, that can be one of the following transaction types:
 - ReadClean
 - ReadShared
 - ReadNotSharedDirty
 - ReadPreferUnique
 - MakeReadUnique
 - CleanUnique
 - ReadNoSnp
 - WriteNoSnp

See [Chapter 6 Exclusive accesses](#) for further details.

In requests, when applicable, the same bits in the packet are used for TagGroupID, PGroupID, and StashGroupID.

For other transactions, the LPID value is permitted, but not required, to indicate the original logical processor that caused a transaction to be issued.

13.10.8 Persistence Group Identifier, PGroupID

This field is used by a Requester to process different sets of CleanSharedPersistSep transactions by grouping them together and identifying each using PGroupID.

Applicable in the CleanSharedPersistSep and Write*CleanShPerSep requests and the Persist and CompPersist responses.

Inapplicable and must be set to zero in all other requests and responses.

In requests, when applicable, the same bits in the packet are used for LPID, TagGroupID, and StashGroupID.

In responses, when applicable, the same bits in the packet are used for DBID, TagGroupID, and StashGroupID.

13.10.9 Stash Node Identifier, StashNID

This field identifies the target of the Stash request. Provides a valid stash target value when the corresponding StashNIDValid bit is asserted. See [Stash target identifiers on page 7-309](#).

Applicable in Stash requests.

Inapplicable and must be zero for all other requests. For ReadNoSnp and ReadNoSnpSep requests, the same bits in the packet are used for ReturnNID.

13.10.10 Stash Node Identifier Valid, StashNIDValid

This field indicates if StashNID field has a valid value. See [Stash target identifiers on page 7-309](#).

Applicable in Stash requests, inapplicable and must be set to zero in all other requests.

Table 13-10 shows the StashNIDValid value encoding.

Table 13-10 StashNIDValid value encoding

StashNIDValid	Description
0	StashNID field value is inapplicable and must be set to zero.
1	The StashNID field in the Request has a valid Stash target.

For permitted combinations of StashNIDValid and StashLPIDValid, see [Table 7-3 on page 7-310](#).

13.10.11 Stash Logical Processor Identifier, StashLPID

This field provides a valid LP target value within the Request Node specified by StashNID. See [Stash target identifiers on page 7-309](#).

Applicable in Stash requests and Stash type Snoop requests.

Inapplicable and must be zero for all other requests. For ReadNoSnp requests, the same bits in the packet are used for ReturnTxnID.

Inapplicable and must be zero for all other snoop requests. For Forwarding snoops, the same bits in the packet are used for FwdTxnID and for SnpDVMOp snoops the same bits in the packet are used for VMIDExt.

13.10.12 Stash Logical Processor Identifier Valid, StashLPIDValid

This field indicates if the StashLPID field has a valid value. See [Stash target identifiers on page 7-309](#).

Applicable in Stash requests and Stash snoop requests, inapplicable and must be set to zero in all other requests.

Table 13-11 shows the StashLPIDValid value encoding.

Table 13-11 StashLPIDValid value encoding

StashLPIDValid	Description
0	StashLPID field value is inapplicable and must be set to zero.
1	The StashLPID field in the Request has a valid Stash target.

For permitted combinations of StashLPIDValid and StashNIDValid, see [Table 7-3 on page 7-310](#).

13.10.13 Stash Group Identifier, StashGroupID

This field is used by a Requester to process different sets of StashOnceSep transactions by grouping them together and identifying each using StashGroupID.

Applicable only in the StashOnceSep request and StashDone response.

Inapplicable and must be set to zero in all other requests and responses.

In requests, when applicable, the same bits in the packet are used for LPID, TagGroupID, and PGroupID.

In responses, when applicable, the same bits in the packet are used for DBID, TagGroupID, and PGroupID.

13.10.14 Transaction Identifier, TxnID

This field provides the transaction identifier of the message. When there are multiple outstanding transactions from a given source node they will each use a unique transaction ID. See [Transaction Identifier, TxnID on page 2-93](#).

The TxnID in a link flit must be zero.

13.10.15 Return Transaction Identifier, ReturnTxnID

This field identifies the value the Subordinate must use in the TxnID field of the CompData, and DataSepResp response. It can be either the TxnID generated by Home for this transaction or the TxnID in the Request packet from the Requester that originated the transaction. See [Return Node Identifier, ReturnNID on page 2-96](#).

Applicable only in ReadNoSnp, ReadNoSnpSep, WriteNoSnp, Combined Write, and Atomic requests from Home to Subordinate.

Inapplicable and must be set to zero for all other requests. For Stash requests, the same bits in the packet are used for StashLPID.

13.10.16 Forwarding Transaction Identifier, FwdTxnID

This field identifies the TxnID field of the original Request associated with the Snoop transaction. See [Forward Transaction Identifier, FwdTxnID on page 2-95](#).

Applicable in Forward-type snoops.

Inapplicable and must be set to zero in all other Snoop requests. For Stash snoops, the same bits in the packet are used for StashLPID and for SnpDVMOp snoops the same bits in the packet are used for VMIDExt.

13.10.17 Data Buffer Identifier, DBID

The value in this field in the response packet from a Completer is used in the TxnID field for CompAck or WriteData sent from the Requester.

In Snoop responses with Data Pull, the DBID value indicates the value to be used in the TxnID field of Data Pull response messages. See [Data Buffer Identifier, DBID on page 2-94](#).

In responses, when applicable, the same bits in the packet are used for PGroupID, StashGroupID, and TagGroupID.

13.10.18 Channel opcodes, Opcode

This field specifies the operation to be carried out. The Opcode encodings are specific to each channel. See:

- [REQ channel opcodes](#)
- [RSP channel opcodes](#) on page 13-432
- [SNP channel opcodes](#) on page 13-433
- [DAT channel opcodes](#) on page 13-434

REQ channel opcodes

[Table 13-12](#) shows the opcodes for the Request channel.

Table 13-12 REQ channel opcodes

Request command		
Opcode[5:0]	Opcode[6] = 0	Opcode[6] = 1
0x00	ReqLCrdReturn	Reserved
0x01	ReadShared	MakeReadUnique
0x02	ReadClean	WriteEvictOrEvict
0x03	ReadOnce	WriteUniqueZero
0x04	ReadNoSnP	WriteNoSnPZero
0x05	PCrdReturn	Reserved
0x06	Reserved	Reserved
0x07	ReadUnique	StashOnceSepShared
0x08	CleanShared	StashOnceSepUnique
0x09	CleanInvalid	Reserved
0x0A	MakeInvalid	Reserved
0x0B	CleanUnique	Reserved
0x0C	MakeUnique	ReadPreferUnique

0x0F	Reserved	Reserved
0x10	Reserved	WriteNoSnPFullCleanSh
0x11	ReadNoSnP Sep	WriteNoSnPFullCleanInv
0x12	Reserved	WriteNoSnPFullCleanShPerSep
0x13	CleanSharedPersistSep	Reserved
0x14	DVMOp	WriteUniqueFullCleanSh
0x15	WriteEvictFull	Reserved
0x16	Reserved	WriteUniqueFullCleanShPerSep
0x17	WriteCleanFull	Reserved

Table 13-12 REQ channel opcodes (continued)

Request command		
Opcode[5:0]	Opcode[6] = 0	Opcode[6] = 1
0x18	WriteUniquePtl	WriteBackFullCleanSh
0x19	WriteUniqueFull	WriteBackFullCleanInv
0x1A	WriteBackPtl	WriteBackFullCleanShPerSep
0x1B	WriteBackFull	Reserved
0x1C	WriteNoSnpPtl	WriteCleanFullCleanSh
0x1D	WriteNoSnpFull	Reserved
0x1E	Reserved	WriteCleanFullCleanShPerSep
0x1F	Reserved	Reserved
0x20	WriteUniqueFullStash	WriteNoSnpPtlCleanSh
0x21	WriteUniquePtlStash	WriteNoSnpPtlCleanInv
0x22	StashOnceShared	WriteNoSnpPtlCleanShPerSep
0x23	StashOnceUnique	Reserved
0x24	ReadOnceCleanInvalid	WriteUniquePtlCleanSh
0x25	ReadOnceMakeInvalid	Reserved
0x26	ReadNotSharedDirty	WriteUniquePtlCleanShPerSep
0x27	CleanSharedPersist	Reserved
0x28 - 0x2F	AtomicStore	Reserved
0x30 - 0x37	AtomicLoad	Reserved
0x38	AtomicSwap	Reserved
0x39	AtomicCompare	Reserved
0x3A	PrefetchTgt	Reserved
0x3B - 0x3F	Reserved	Reserved

Note

Prior to CHI Issue E, the following requests were not supported:

- ReadPreferUnique
- MakeReadUnique
- StashOnceSep
- WriteEvictOrEvict
- WriteNoSnpZero
- WriteUniqueZero
- Combined Write

Table 13-13 shows the sub-opcodes for AtomicStore and AtomicLoad.

Table 13-13 Sub-codes for AtomicStore and AtomicLoad			
Opcode[5:3]		Opcode[2:0]	Operation
AtomicStore	AtomicLoad		
101	110	000	ADD
		001	CLR
		010	EOR
		011	SET
		100	SMAX
		101	SMIN
		110	UMAX
		111	UMIN

RSP channel opcodes

Table 13-14 shows the opcodes for the Response channel.

Table 13-14 RSP channel opcodes encoding

Opcode[4:0]	Response
0x0	RespLCrdReturn
0x1	SnpResp
0x2	CompAck

0x10	StashDone
0x11	CompStashDone
0x12-0x13	Reserved
0x14	CompCMO
0x15-0x1F	Reserved

Note

Prior to CHI Issue E, the following responses were not supported:

- DBIDRespOrd
- TagMatch
- StashDone
- CompStashDone
- CompCMO

SNP channel opcodes

Table 13-15 shows the opcodes for the Snoop channel.

Table 13-15 SNP channel opcodes encoding

Opcode[4:0]	Snoop command
0x00	SnpLCrdReturn
0x01	SnpShared
0x02	SnpClean
0x03	SnpOnce
0x04	SnpNotSharedDirty
0x05	SnpUniqueStash
0x06	SnpMakeInvalidStash
0x07	SnpUnique
0x08	SnpCleanShared
0x09	SnpCleanInvalid
0x0A	SnpMakeInvalid
0x0B	SnpStashUnique
0x0C	SnpStashShared
0x0D	SnpDVMOp
0x0E - 0x0F	Reserved
0x10	SnpQuery
0x11	SnpSharedFwd
0x12	SnpCleanFwd
0x13	SnpOnceFwd
0x14	SnpNotSharedDirtyFwd
0x15	SnpPreferUnique
0x16	SnpPreferUniqueFwd
0x17	SnpUniqueFwd
0x18 - 0x1F	Reserved

Note

Prior to CHI Issue E, the following Snoop requests were not supported:

- SnpPreferUnique
- SnpPreferUniqueFwd
- SnpQuery

DAT channel opcodes

Table 13-16 shows the opcodes for the Data channel.

Table 13-16 DAT channel opcodes encoding

Opcode[3:0]	Data command
0x0	DataLCrdReturn
0x1	SnpRespData
0x2	CopyBackWrData
0x3	NonCopyBackWrData
0x4	CompData
0x5	SnpRespDataPtl
0x6	SnpRespDataFwded
0x7	WriteDataCancel
0x8 - 0xA	Reserved
0xB	DataSepResp
0xC	NCBWrDataCompAck
0xD-0xF	Reserved

13.10.19 Deep persistence, Deep

This field is used by the Requester to indicate that the Persist response must not be sent until all earlier writes are written to the final destination.

Applicable in the CleanSharedPersist* request and Combined Write request with CleanSharedPersistSep.

Inapplicable and must be set to zero in all other requests.

When Deep is deasserted:

- The Completer must send Persist response after all the earlier writes have reached the PoP.
 - The PoP is the point at which it is guaranteed that sufficient time is available to make the data persistent after loss of power.

When Deep is asserted:

- The Completer must send the Persist response only after all earlier writes are written to the final destination, not just the PoP.
 - The final destination is the point at which no time is required to make the data persistent after the loss of power, thus preserving data even when battery failure occurs.

13.10.20 Address, Addr

This field specifies the address associated with the message.

This specification supports a PA of 44 to 52 bits. The address is carried in Addr field in the REQ and SNP channel.

The width of the field is defined by the Req_Addr_Width parameter. The field width is the same value of the parameter in REQ channel, Addr[(43-51):0], and is three less than the parameter value in the SNP channel, Addr[(43-51):3].

The Addr field is utilized in the REQ and SNP channels in the following manner.

- For Read, PrefetchTgt, Dataless, Write, and Atomic transactions, the Addr field includes the address of the memory location being accessed. This starts with Addr[0] mapped to bit zero of Addr.
 - For a snoop request, except SnpDVMOp, the Addr field includes the address of the location being snooped. This starts with Addr[3] mapped to bit zero of Addr.
 - Addr[(43-51):6] is the cache line address. It is sufficient to uniquely identify the cache line to be accessed by the snoop.
 - Addr[5:4] identifies the critical chunk being accessed by the transaction. See [Critical Chunk Identifier on page 2-148](#). It is recommended that the snooped cache returns the data in wrap order with the critical chunk returned first.
- Note**
- Addr[3] in the REQ channel, that is Addr[0] in SNP channel, is supplied but is not used by a snoop request.
- For a DVMOp and SnpDVMOp request, the Addr field is used to carry information related to a DVM operation. See [Chapter 8 DVM Operations](#).
 - The Addr value is not used for PCrdReturn transaction and must be set to zero.

13.10.21 Non-secure, NS

This field indicates a Non-secure access or a Secure access. See [Non-secure bit on page 2-133](#).

[Table 13-17](#) shows the NS field value encoding.

Table 13-17 NS value encoding

NS	Description
0	Secure access
1	Non-secure access

13.10.22 Size of transaction data, Size

This field specifies the size of the data associated with the transaction. See [Data size on page 2-142](#).

[Table 13-18](#) shows the Size field value encodings.

Table 13-18 Size field value encodings

Size[2:0]	Bytes
0b000	1
0b001	2
0b010	4

Table 13-18 Size field value encodings (continued)

Size[2:0]	Bytes
0b011	8
0b100	16
0b101	32
0b110	64
0b111	Reserved

13.10.23 Memory Attribute, MemAttr

This field is associated with the transaction.

[Table 13-19](#) shows the MemAttr value encodings.

Table 13-19 MemAttr value encodings

MemAttr[3:0]	Description	0	1
[3]	Allocate hint bit. Indicates whether or not the cache receiving the transaction is recommended to allocate the transaction:	Recommend that it does not allocate	Recommend that it allocates
[2]	Cacheable bit. Indicates a Cacheable transaction for which the cache, when present, must be looked up in servicing the transaction:	Non-cacheable. Looking up a cache is not required	Cacheable. Looking up a cache is required.
[1]	Device bit. Indicates if the memory type associated with the transaction is Device or Normal:	Normal memory type	Device memory type
[0]	Early Write Acknowledge (EWA) bit. Specifies the EWA status for the transaction:	EWA not permitted	EWA permitted

See [Memory Attributes](#) on page 2-134.

13.10.24 Snoop Attribute, SnpAttr

This field specifies the snoop attribute associated with the transaction.

[Table 13-20](#) shows the SnpAttr value encoding.

Table 13-20 SnpAttr value encoding

SnpAttr	Description
0	Non-snoopable
1	Snoopable

See [Snoop Attribute, SnpAttr](#) on page 2-139.

13.10.25 Do Direct Write Transfer, DoDWT

The characteristics of this field are:

- Only applicable in WriteNoSnPFull, WriteNoSnPtl, and Combined Write requests from Home to Subordinate.
- It is inapplicable and must be set to zero in all other requests.
- The bit shares the same field as SnPAttr.

Table 13-21 shows the DoDWT value encoding.

Table 13-21 DoDWT value encoding

DoDWT	DBIDResp.TgtID value	DBIDResp.TxnID value
0	Set to the SrcID value of the request	Set to TxnID value in the request
1	Set to the ReturnNID value in the request	Set to the ReturnTxnID value in the request

See [Immediate write on page 2-55](#) and [Combined Immediate Write and CMO on page 2-62](#).

13.10.26 Likely Shared, LikelyShared

This field indicates whether the requested data is likely to be shared with another Request Node. See [Likely Shared on page 2-139](#).

Table 13-22 shows the LikelyShared field value encoding.

Table 13-22 LikelyShared value encoding

LikelyShared	Description
0	Not likely to be shared by another RN
1	Likely to be shared by another RN

13.10.27 Ordering requirements, Order

This field specifies the ordering requirements for a transaction. See [Ordering on page 2-121](#) for more information on the ordering requirements.

Table 13-23 on page 13-439 shows the Order field value encodings.

Table 13-23 Order value encodings

Order[1:0]	Description	Permitted between
0b00	No ordering required	All
0b01	Request accepted	HN-F to SN-F and HN-I to SN-I
	Reserved	RN to HN
0b10	Request Order/Ordered Write Observation	RN to HN ^a
	Request Order	HN-I to SN-I
	Reserved	HN-F to SN-F
0b11	Endpoint Order	RN to HN and HN-I to SN-I
	Reserved	HN-F to SN-F

- a. Request Order when ExpCompAck = 0.
Ordered Write Observation when ExpCompAck = 1.

13.10.28 Exclusive, Excl

This field indicates that the corresponding transaction is an Exclusive-type transaction. The Exclusive bit must only be used with the following transactions:

- ReadNotSharedDirty
- ReadShared
- ReadClean
- ReadPreferUnique
- CleanUnique
- MakeReadUnique
- ReadNoSnP
- WriteNoSnP

Table 13-24 shows the Excl value encoding.

Table 13-24 Excl value encoding

Excl	Description
0	Normal transaction
1	Exclusive transaction

See [Exclusive transactions on page 6-296](#).

13.10.29 Endian

This field indicates the endianness of Data in an Atomic transaction. See [Endianness on page 2-147](#).

Applicable in Atomic requests, inapplicable in all other requests and must be set to zero.

Table 13-25 shows the Endian value encoding.

Table 13-25 Endian value encoding

Endian	Description
0	Little Endian
1	Big Endian

13.10.30 Allow Retry, AllowRetry

This field specifies that the request is being sent without a P-Credit and that the target can determine if a retry response is given. See [Transaction Retry mechanism on page 2-156](#).

Table 13-26 shows the AllowRetry value encoding.

Table 13-26 AllowRetry value encodings

AllowRetry	Description
0	RetryAck response not permitted
1	RetryAck response permitted

13.10.31 Expect Completion Acknowledge, ExpCompAck

This field indicates that the transaction will include a CompAck response.

Table 13-27 shows the ExpCompAck value encoding.

Table 13-27 ExpCompAck value encoding

ExpCompAck	Description
0	Transaction does not include a CompAck response
1	Transaction includes a CompAck response

13.10.32 SnoopMe

This field indicates that the Home must determine whether to send a snoop to the Requester. See [Atomic transactions on page 2-74](#).

Only applicable in Atomic requests.

Table 13-28 shows the SnoopMe value encoding.

Table 13-28 SnoopMe value encoding

SnoopMe	Description
0	Home is permitted, but not required, to send a snoop to the Requester.
1	Home must send a Snoop to the Requester if it determines the cache line might be present at the Requester.

13.10.33 Return to Source, RetToSrc

This field requests the Snoopee to return a copy of the cache line to the Home.

Applicable in all snoops except SnpDVMOp.

For RetToSrc bit semantics see [Returning Data with Snoop response on page 4-251](#).

13.10.34 Data Pull, DataPull

This field indicates the inclusion of a Read request, also referred to as a Data Pull, in the Snoop response. See [Snoop requests and Data Pull on page 7-304](#).

Applicable in SnpResp and SnpRespData response to a Stash request, not applicable in all other Snoop responses.

When the DataPull bit is set in a SnpRespData message, it must be set in all packets of that response message.

Table 13-29 shows the DataPull field value encodings.

Table 13-29 DataPull value encodings

DataPull[2:0]	Description	Comment
0b000	No Read	Inclusion of Data Pull in the Snoop response
0b001	Read	
0b010- 0b111	-	Reserved

13.10.35 Do not transition to SD state, DoNotGoToSD

This field is an attribute in a Snoop request indicating if a Snoopee is required to not transition to SD state. See [Do not transition to SD on page 4-252](#).

Applicable, and can take any value in:

- SnpOnce, SnpOnceFwd
- SnpClean, SnpCleanFwd
- SnpNotSharedDirty, SnpNotSharedDirtyFwd
- SnpShared, SnpSharedFwd
- SnpPreferUnique, SnpPreferUniqueFwd

Applicable, and must be set to 1 in:

- SnpStashShared, SnpStashUnique
- SnpUnique, SnpUniqueFwd, SnpUniqueStash
- SnpCleanShared
- SnpCleanInvalid
- SnpMakeInvalid, SnpMakeInvalidStash

Inapplicable, and must be set to zero in:

- SnpQuery
- SnpDVMOp

[Table 13-30](#) shows the DoNotGoToSD value encoding.

Table 13-30 DoNotGoToSD value encoding

DoNotGoToSD	Description
0	Permitted to transition to SD state.
1	Transitioning to SD state is not permitted. If already in SD state, SD state must be exited in response to the snoop. The bit value can be ignored by the Snoopee if the Snoop request is SnpOnce or SnpOnceFwd.

13.10.36 Protocol Credit Type, PCrdType

This field indicates the type of credit being granted or returned. See [Transaction Retry mechanism on page 2-156](#).

[Table 13-31](#) shows the PCrdType value encodings.

Table 13-31 PCrdType value encodings

PCrdType	Description
0x0 - 0xF	P-Credit type 0 to 15 respectively.

13.10.37 Tag Operation, TagOp

This field indicates the operation to be performed on the tags present in the corresponding DAT channel.

Table 13-32 shows the TagOp value encodings.

Table 13-32 TagOp value encodings

TagOp[1:0]	Tag Operation	Description
0b00	<i>Invalid</i>	The tags are not valid.
0b01	<i>Transfer</i>	<ul style="list-style-type: none"> The tags are Clean. Tag Match does not need to be performed. All tags corresponding to data in the packet must be transferred. For Snoopable transactions, partial tag transfer is not supported. TU field is not applicable and must be set to zero.
0b10	<i>Update</i>	<ul style="list-style-type: none"> The Allocation Tag values have been updated and are Dirty. The Tags in memory should be updated. Only the Tags that have TU asserted must be updated.
0b11	<i>Match</i> <i>Fetch</i>	<ul style="list-style-type: none"> <i>Match</i>: <ul style="list-style-type: none"> — The Physical Tags in the write must be checked against the Allocation Tag values obtained from memory. — The Match Tag operation must be enabled for only those tags that have BE asserted. — TU field is not applicable and must be set to zero. <i>Fetch</i>: <ul style="list-style-type: none"> — Tags must be fetched. — All tags must be fetched. — Permitted, but not required, to fetch valid data.

TagOp value in a Retry request must be the same as in the original request.

13.10.38 Tag

Tag[4*n-1:0]. This field provides n sets of 4-bit tags, each associated with a 16-byte, aligned address location.

[Tag[((4*n)-1) : 4*(n-1)] corresponds to Data[((128*n)-1) : 128*(n-1)]

13.10.39 Tag Update, TU

TU[n-1:0]. This field indicates which of the Allocation Tags must be updated. There is one TU bit for each tag. Only valid in Snoop responses and Write transactions which update the Allocation Tags. Must be set to zero in all other transactions.

TU[n-1] corresponds to Tag[(4*n)-1 : 4*(n-1)]

13.10.40 Tag Group Identifier, TagGroupID

This field is used by a Requester to process different sets of TagMatch responses by grouping the corresponding requests together and identifying each group using TagGroupID. The precise contents of TagGroupID are IMPLEMENTATION DEFINED. Typically, TagGroupID is expected to contain an Exception Level, TTBR value, and CPU identifier.

TagGroupID is applicable in requests where TagOp is set to *Match* and in a TagMatch response.

In requests, when applicable, the same bits in the packet are used for LPID, PGroupID, or StashGroupID.

In responses, when applicable, the same bits in the packet are used for DBID, PGroupID, or StashGroupID.

13.10.41 Trace Tag, TraceTag

This field is a bit in a packet used to tag the packets associated with a transaction for tracing purposes.

[Table 13-33](#) shows the TraceTag field value encoding.

Table 13-33 TraceTag value encoding

TraceTag	Description
0	Packet is not tagged.
1	Packet is tagged.

See [Chapter 11 System Debug, Trace, and Monitoring](#).

13.10.42 Memory System Performance Resource Partitioning and Monitoring, MPAM

This field is used to efficiently utilize the memory resources among users and to monitor their use. See [MPAM on page 11-373](#).

13.10.43 Virtual Machine Identifier Extension, VMIDExt

This field is used to extend VMID value from 8-bits to 16-bits. See [DVMOp payload on page 8-323](#).

13.10.44 Response status, Resp

This field must have the same value in all data flits of a multi-flit data transfer.

[Table 13-34](#) shows the Resp value encodings.

Table 13-34 Resp value encodings

Resp[2:0]	Description
Resp[2]	PassDirty. Indicates that the data included in the response message is Dirty with respect to memory and that the responsibility of writing back the cache line is being passed to the recipient of the response message. 0 Returned data is not Dirty. 1 Returned data is Dirty and the responsibility of writing back the cache line is being passed on.
Resp[1:0]	For snoop responses, this field indicates the final state of the snooped RN-F. For completion responses, this field indicates the final state in the RN. For WriteData responses, this field indicates the state of the data in the RN when the data is sent. For TagMatch responses, Resp[0] alone indicates a Tag Match pass or fail.

Table 13-35 shows the valid Resp value encodings.

Table 13-35 Valid Resp value encodings for different message types

Response Type	Resp[2:0]	State	Notes
Snoop responses	0b000	I	Final state of the snooped RN-F.
	0b001	SC	
	0b010	UC, UD	
	0b011	SD	
	0b100	I_PD	Final state of the snooped RN-F. Responsibility for updating memory is passed to Home.
	0b101	SC_PD	
	0b110	UC_PD	
	0b111	-	Reserved.
Comp responses	0b000	I	Final state of the requesting RN-F.
	0b001	SC	
	0b010	UC	
	0b011	-	Reserved.
	0b100	-	
	0b101	-	
	0b110	UD_PD	Final state of the requesting RN-F. Responsibility for updating memory is passed to the Requester.
	0b111	SD_PD	
WriteData responses	0b000	I	The cache state in the response is imprecise and must be ignored.
	0b001	SC	State of the cache line at the RN-F when data is sent.
	0b010	UC	
	0b011	-	Reserved.
	0b100	-	
	0b101	-	
	0b110	UD_PD	State of the cache line at the RN-F when data is sent. Responsibility for updating memory is passed to Home.
	0b111	SD_PD	
TagMatch responses	0b000	Fail	Part of the Tag Match operation.
	0b001	Pass	
	0b010 - 0b111	-	Reserved.

13.10.45 Forward State, FwdState

This field indicates the state in the CompData sent from the Snoopee to the Requester. Applicable in SnpRespFwdded and SnpRespDataFwdded, inapplicable in all other Snoop responses and must be set to zero.

[Table 13-36](#) shows the FwdState value encodings.

Table 13-36 FwdState value encodings

FwdState[2:0]	Description
FwdState[2]	PassDirty.
0	Forwarded data is not Dirty.
1	Forwarded data is Dirty and the responsibility of writing back the cache line is passed on to the Requester.
FwdState[1:0]	Indicates the final state at the Requester. See Table 13-37 .

[Table 13-37](#) enumerates the FwdState value encodings.

Table 13-37 Valid FwdState value encodings

FwdState[2:0]	State	Comment
0b000	I	Final state at the Requester.
0b001	SC	
0b010	UC	
0b011	-	Reserved.
0b100	-	
0b101	-	
0b110	UD_PD	Final state at the Requester. Responsibility for updating memory is passed to the Requester.
0b111	SD_PD	

13.10.46 Completer Busy, CBusy

This field is a mechanism for the Completer of a transaction to indicate its current level of activity. The CBusy value encodings are IMPLEMENTATION DEFINED. See [Completer Busy on page 11-375](#).

13.10.47 Response Error, RespErr

This field indicates the error status of the response. See [Chapter 9 Error Handling](#).

[Table 13-38](#) shows the RespErr value encodings.

Table 13-38 RespErr value encodings

RespErr[1:0]	Description
0b00	Normal Okay. Indicates that either: <ul style="list-style-type: none"> The Normal access was successful. The Exclusive access failed.
0b01	Exclusive Okay. Indicates that either the read or write portion of an Exclusive access was successful.
0b10	Data Error.
0b11	Non-data Error.

13.10.48 Data payload, Data

This field is the data payload that is being transported in a Data packet.

The following data bus widths are supported:

- 128-bit
- 256-bit
- 512-bit

See [Data packetization on page 2-144](#).

13.10.49 Critical Chunk Identifier, CCID

This field indicates the critical 128-bit chunk of the data that is being requested. See [Critical Chunk Identifier on page 2-148](#).

[Table 13-39](#) shows the CCID value encodings.

Table 13-39 CCID value encodings

CCID[1:0]	Critical data chunk
0b00	Data[127:0]
0b01	Data[255:128]
0b10	Data[383:256]
0b11	Data[511:384]

13.10.50 Data Identifier, DataID

This field indicates the relative position of the data chunk within the 512-bit cache line that is being transferred. See [Data packetization on page 2-144](#).

[Table 13-40](#) shows the DataID value encodings.

Table 13-40 DataID and the bytes within a packet for different data widths

DataID	Data Width		
	128-bit	256-bit	512-bit
0b00	Data[127:0]	Data[255:0]	Data[511:0]
0b01	Data[255:128]	Reserved	Reserved
0b10	Data[383:256]	Data[511:256]	Reserved
0b11	Data[511:384]	Reserved	Reserved

13.10.51 Byte Enable, BE

This field indicates if the byte of data corresponding to this byte enable bit is valid. The BE field is defined for write data, DVM payload, and Snoop response data transfers. For Read response data transfers, this field is inapplicable and can take any value. It consists of a bit for each data byte in the DAT flit. See [Byte Enables on page 2-143](#).

[Table 13-41](#) shows the BE value encodings.

Table 13-41 BE value encodings

BE	Byte enable
0	Corresponding byte of data is not valid.
1	Corresponding byte of data is valid.

13.10.52 Data check, DataCheck

This field is used to supply the DataCheck bit for the corresponding byte of Data. See [Data Check on page 9-356](#).

13.10.53 Poison

This field indicates if the 64-bit chunk of data corresponding to a Poison bit is poisoned, that is, has an error, and must not be consumed. See [Poison on page 9-355](#).

[Table 13-42](#) shows the Poison value encodings.

Table 13-42 Poison value encodings

Poison	Description
0	Corresponding 64-bit chunk is not poisoned.
1	Corresponding 64-bit chunk is poisoned.

13.10.54 Data source, DataSource

This field identifies the Sender of the data response. See [DataSource value assignment](#) on page 11-368.

Applicable in CompData and DataSepResp responses in Read and Atomic transactions, and SnpRespData and SnpRespDataPtl responses in Non-stash type Snoop transactions. DataSource is not applicable and must be set to zero in all other responses.

[Table 13-43](#) shows the DataSource value encodings.

Table 13-43 DataSource value encodings

DataSource	Description	Comment
0b0000	DataSource is not supported	Applicable only to a non-memory component
0b0001 - 0b0101	IMPLEMENTATION DEFINED	See Suggested DataSource values on page 11-369
0b0110	PrefetchTgt was useful	Indication from memory that the earlier sent prefetch was useful or memory received a prefetch.
0b0111	PrefetchTgt was not useful	Indication from memory that the earlier sent prefetch was not useful or memory did not receive a prefetch.
0b1000 - 0b1111	IMPLEMENTATION DEFINED	-

13.10.55 System Level Caches Replacement Hint, SLCRepHint

This field forwards cache replacement hints from the Requesters to the SLC in the interconnect, See [SLC replacement hint](#) on page 11-371.

13.10.56 Reserved for Customer Use, RSVDC

This field in a Protocol flit can take any value. Propagation of this field through the interconnect is IMPLEMENTATION DEFINED. There is no defined relationship between RSDVC field values in different packets of a transaction.

This field is applicable in the REQ and DAT channels as follows:

- The presence of this field is optional.
- The permitted field widths are 4-bit, 8-bit, 12-bit, 16-bit, 24-bit, and 32-bit.
- The field widths:
 - Can be different between REQ and DAT channels.
 - Need not be the same across all REQ channels in the system.
 - Need not be the same across all DAT channels in the system.

When connecting Tx and Rx flit interfaces that have mismatched RSVDC widths:

- The corresponding lower-order bits of the RSVDC field must be connected at each side of the interface.
- The higher-order RSVDC bits at the RX interface that do not have corresponding bits at the TX interface must be tied LOW.

13.11 Link flit

A link flit is used to return L-Credits to the receiver during a link deactivation sequence. Link flits originate at a link Transmitter and terminate at the link Receiver on the other side of the link.

A link flit is identified by a zero value in the Opcode field. The TxnID field of the link flit is required to be zero. The remaining fields are not used and can take any value. See [Channel opcodes, Opcode on page 13-429](#) for the link flit type encoding.

Chapter 14

Link Handshake

This chapter describes the link handshake requirements. It contains the following sections:

- *Clock, and initialization on page 14-452*
- *Link layer Credit on page 14-453*
- *Low power signaling on page 14-454*
- *Flit level clock gating on page 14-455*
- *Interface activation and deactivation on page 14-456*
- *Transmit and receive link Interaction on page 14-462*
- *Protocol layer activity indication on page 14-468*

14.1 Clock, and initialization

This section specifies the AMBA 5 CHI requirement for global clock and reset signals.

14.1.1 Clock

This specification does not define a specific clocking microarchitecture. It is expected that all devices, interconnects, and so on, includes one or more clocks that can be relied upon by other Link layer functions that require synchronous communication. A generic clock signal is referred to as **CLK** in the following sections, where applicable.

14.1.2 Reset

This specification does not define a specific reset microarchitecture. It is expected that all devices, interconnects, and so on, include a specific reset deassertion event that can be relied upon by other Link layer functions. A generic reset signal is referred to as **RESETn** in the following sections, where applicable.

14.1.3 Initialization

During reset the following interface signals must be deasserted by the component:

- **TX***LCRDV**.
- **TX***FLITV**.
- **TXLINKACTIVEREQ** and **RXLINKACTIVEACK**.

The earliest point after reset that it is permitted to begin driving these signals HIGH is at a rising **CLK** edge after **RESETn** is HIGH.

All other signals can take any value.

14.2 Link layer Credit

This section describes the *Link layer Credit* (L-Credit) mechanism. Information is transferred across an interface channel by the use of L-Credits. To transfer one flit from the Transmitter to the Receiver, the Transmitter must have obtained an L-Credit.

14.2.1 L-Credit flow control

An L-Credit is sent from the Receiver to the Transmitter by asserting the appropriate **LCRDV** signal for a single clock cycle. There is one **LCRDV** signal for each channel. See [Channel interface signals on page 13-414](#) for the **LCRDV** signal naming for each channel.

Each transfer of a flit from the Transmitter to the Receiver consumes one L-Credit.

The minimum number of L-Credits that a Receiver can provide is 1. The maximum number of L-Credits that a Receiver can provide is 15.

A Receiver must guarantee that it can accept all the flits for which it has issued L-Credits.

When the link is active, the Receiver must provide L-Credits in a timely manner without requiring any action on the part of the Transmitter.

———— **Note** —————

An L-Credit cannot be used in the cycle it is received.

—————

14.3 Low power signaling

This section describes the signaling used to enhance the low power operation of the interface. There are several different levels of operation:

Flit Level Clock Gating

This technique is used to provide a cycle-by-cycle indication of the activity of each of the channels of the interface. For each channel, an additional signal is provided to indicate if a transfer might occur in the following cycle. This signaling permits local clock gating of certain registers associated with the interface.

Link Activation

Link activation and deactivation are supported to permit the interface to be taken to a safe state, so that both-sides of the interface can enter a low power state that permits them to be either clock-gated or power-gated.

Protocol Activity Indication

The Protocol layer activity indication is used by components to indicate if there are ongoing transactions in progress. The Protocol layer activity indication can be used to influence the decision to use other low power techniques.

14.4 Flit level clock gating

The **FLITPEND** signal associated with a channel is used to indicate if a valid flit is going to be sent in the next clock cycle. There is one **FLITPEND** signal for each channel. See [Channel interface signals on page 13-414](#) for the **FLITPEND** signal naming for each channel.

The requirements for the use of **FLITPEND** are:

- It is required that the signal is asserted exactly one cycle before a flit is sent from the Transmitter.
- When asserted, it is permitted, but not required, that the Transmitter sends a flit in the next cycle.
- When deasserted, it is required that the Transmitter does not send a flit in the next cycle.
- A Transmitter is permitted, but not required, to keep the signal permanently asserted. A Transmitter might do this, for example, if it is unable to determine in advance when a flit is to be sent.
- A Transmitter is permitted, but not required, to assert this signal when it does not have an L-Credit.
- A Transmitter is permitted, but not required, to assert and then deassert this signal without sending a flit.

[Figure 14-1](#) shows an example of the use of the **FLITPEND** signal.

Figure 14-1 FLITPEND indicating a valid flit in next cycle

14.5 Interface activation and deactivation

A mechanism is provided for an entire interface to move between a full running operational state and a low power state. When moving between operational states, including when exiting from reset, it is important that the exchange of L-Credits. The exchange of Link flits is carefully controlled to avoid the loss of flits or credits.

On exit from reset, or when moving to a full running operational state, the interface starts in an idle state and the transfer of flits can only commence when L-Credits have been exchanged. L-Credits can only be exchanged when the Sender of the credits knows the Receiver is ready to receive them.

A two-signal, four-phase, handshake mechanism is used. This two signal interface is used for all channels traveling in the same direction, rather than being required for each individual channel. An entire interface uses a total of four signals, two signals are used for all the transmit channels and two signals are used for all the receive channels.

14.5.1 Request and Acknowledge handshake

For the purposes of description, the two signal Request and Acknowledge signaling is described using the signal names **LINKACTIVEREQ** and **LINKACTIVEACK**.

This section describes the operation of the **LINKACTIVEREQ** and **LINKACTIVEACK** handshake pairs for all channels moving in one direction. [Transmit and receive link Interaction on page 14-462](#) describes the interaction between the handshake pairs for the transmit channels and those for the receive channels.

For a single channel, or group of channels traveling in the same direction, [Figure 14-2](#) shows the relationship between the Payload, Credit, **LINKACTIVEREQ**, and **LINKACTIVEACK** signals.

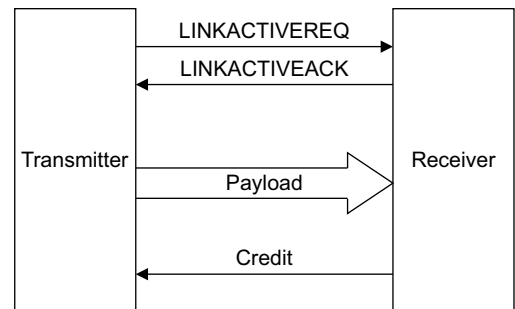

Figure 14-2 Relationship between Payload, Credit, and LINKACTIVE signals

As [Figure 14-2](#) shows, during normal operation the Transmitter, which sends the payload flits, requires a credit before it can send a flit. A credit is passed from the Receiver when it has resources available to accept a flit:

- On exit from reset, credits are held by the Receiver and must be passed to the Transmitter before flit transfer can begin.
- During normal operation, there is an ongoing exchange of flits and credits between the two sides of the interface.
- Before entering a low power state, the sending of payload flits must be stopped and all credits must be returned to the Receiver. This effectively returns the interface to the same state that it was at immediately after reset.

Four states are defined for the interface operation:

RUN	There is an ongoing exchange of flits and credits between the two components.
STOP	The interface is in a low power state and it is not operational. All credits are held by the Receiver and the Transmitter is not permitted to send any flits.
ACTIVATE	This state is used when moving from the STOP state to the RUN state.
DEACTIVATE	This state is used when moving from the RUN state to the STOP state.

RUN and STOP are stable states. When one of these states is entered, a channel can remain in this state for an indefinite period.

DEACTIVATE and ACTIVATE are transient states. It is expected that when one of these states is entered, a channel moves to the next stable state in a relatively short period.

———— **Note** ————

The specification does not define a maximum period in a transient state, but it is expected that for any given implementation it is deterministic.

The state is determined by the **LINKACTIVEREQ** and **LINKACTIVEACK** signals. [Figure 14-3](#) shows the relationship between the four states.

Figure 14-3 Request and Acknowledge handshake states

[Table 14-1](#) shows the mapping of the states to the **LINKACTIVEREQ** and **LINKACTIVEACK** signals.

Table 14-1 Mapping of states to the LINKACTIVE signals

State	LINKACTIVEREQ	LINKACTIVEACK
STOP	0	0
ACTIVATE	1	0
RUN	1	1
DEACTIVATE	0	1

[Table 14-2 on page 14-458](#) describes the behavior of both the Transmitter and the Receiver of a single link for each of the four states.

Table 14-2 Behavior for each Request and Acknowledge state

State	Transmitter behavior	Receiver behavior
STOP	<p>The Transmitter has no credits and must not send any flits.</p> <p>The Transmitter is guaranteed not to receive any credits.</p> <p>The Transmitter must assert LINKACTIVEREQ to move to the ACTIVATE state if it has flits to send.</p>	<p>The Receiver is guaranteed not to receive any flits.</p> <p>The Receiver must not send any credits.</p>
ACTIVATE (ACT)	<p>The Transmitter must not send any flits.</p> <p>The Transmitter must be prepared to receive credits in this state, although it must not use them until in the RUN state.</p> <p>The Transmitter remains in the ACTIVATE state while it is waiting for the Receiver to acknowledge the move to the RUN state.</p> <p>———— Note ————</p> <p>The Transmitter will only receive credits in the ACTIVATE state when there is a race between the Receiver sending credits and asserting LINKACTIVEACK to move to the RUN state.</p>	<p>The Receiver is guaranteed not to receive any flits.</p> <p>The Receiver must not send any credits.</p> <p>The ACTIVATE state is a transient state and the Receiver controls the move to the RUN state by asserting LINKACTIVEACK.</p> <p>The Receiver must assert LINKACTIVEACK and move to the RUN state before sending credits. It is permitted, but not required, to assert LINKACTIVEACK and send a credit in the same cycle.</p> <p>———— Note ————</p> <p>It can appear that a Receiver has sent credits in the ACTIVATE state if there is a race between the Receiver sending credits and asserting LINKACTIVEACK to move to the RUN state.</p>
RUN	<p>The Transmitter can receive credits.</p> <p>The Transmitter can send flits when it has credits available.</p> <p>The Transmitter deasserts LINKACTIVEREQ to exit from this state if it wants to move to a low power state.</p>	<p>The Receiver can receive flits corresponding to the credits it has sent.</p> <p>The Receiver sends credits when it has resources available to accept further flits.</p> <p>The Receiver must remain in the RUN state until it observes the deassertion of LINKACTIVEREQ.</p>
DEACTIVATE (DEACT)	<p>The Transmitter must return credits using Protocol flits or L-Credit return flits.</p> <p>It is recommended that the Transmitter enters the DEACTIVATE state only when it has no more Protocol flits to send. Therefore, it is expected that the Transmitter returns credits using only L-Credit return flits.</p> <p>The Transmitter must be prepared to continue receiving credits. For each additional credit received it must send an L-Credit return flit to return the credit.</p> <p>The Transmitter remains in the DEACTIVATE state while it is waiting for the Receiver to acknowledge the move to the STOP state. At this point, it is guaranteed to receive no more credits.</p>	<p>During this state, the Receiver stops sending credits and collects all returned credits.</p> <p>The Receiver must be prepared to receive flits, other than Link flits to return credits, in this state. This is not expected, but can occur.</p> <p>The Receiver is permitted, but not required, to send credits when first entering this state. However, it must have stopped sending credits and had all credits returned before exiting this state.</p> <p>The Receiver receives L-Credit return flits until all credits are returned.</p> <p>The Receiver must wait for all credits to be returned before deasserting LINKACTIVEACK.</p> <p>———— Note ————</p> <p>The Receiver will only receive flits in the DEACTIVATE state when there is a race between the Transmitter sending the last remaining flits and deasserting LINKACTIVEREQ to move to the DEACTIVATE state.</p>

Table 14-5 on page 14-466 summarizes the required behavior described in detail in Table 14-2 on page 14-458.

Table 14-3 Summary of behavior for each Request and Acknowledge state

State	Transmitter	Receiver
STOP	Must not send flits. Will not receive credits.	Must not send credits. Will not receive flits.
ACT	Must not send flits. Must accept credits.	Must not send credits. Will not receive flits.
RUN	Can send flits. Must accept credits.	Must accept flits. Can send credits.
DEACT	Expected to send L-Credit return flits. Can send any flits. Must accept credits. Must return credits.	Must accept flits. Must stop sending credits.

Response to new state

When moving to a new state, where the state change has been initiated by the other-side of the interface, a component might be required to change its behavior.

If the state change requires a component to start sending flits or credits, there is no defined limit on the time taken for the component to start the new behavior. This new behavior will only occur in the new state.

If the state change requires a component to stop sending flits or credits, the component is permitted to take some time to respond. In this scenario, it is possible to see behavior when first entering a new state which is not expected within that state.

The state change from RUN to DEACTIVATE is the point at which flits and credits stop being sent.

Flits are sent by the Transmitter, which is also the component that determines the state change, and therefore the Transmitter can ensure flits are not sent after the state change.

Credits are sent by the Receiver, but that component does not determine the state change. The Receiver might take some time to react to the state change and therefore it is possible for credits to be sent when first entering the DEACTIVATE state.

The protocol requires that the Receiver has stopped sending credits and has had all credits returned before it signals the change from DEACTIVATE to STOP.

Determining when to move to **ACTIVATE** or **DEACTIVATE**

For a given channel, or set of channels in the same direction, the Transmitter is always responsible for initiating the state change from RUN to STOP, or from STOP to RUN.

The Transmitter itself can determine that a state change is needed. This can happen through various mechanisms. The following examples are not exhaustive:

- The Transmitter can determine that it has flits to send, so must move from STOP to RUN.
- The Transmitter can determine that it has no activity to perform for a significant period, so can move from RUN to STOP.
- The Transmitter can observe an independent sideband signal that indicates it should move either from RUN to STOP, or from STOP to RUN.
- The Transmitter can determine that a transaction is not fully complete and therefore the channels should remain in RUN state until all activity has completed.
- The Transmitter can observe a state change on the channel, or set of channels, that are used in the opposite direction. See [Transmit and receive link Interaction on page 14-462](#).

Multiple channels in the same direction

Figure 14-4 shows an example of a multiple channel interface, also referred to as a Link, that transfers payload flits in the same direction. A single pair of **LINKACTIVEREQ** and **LINKACTIVEACK** signals are used for all channels.

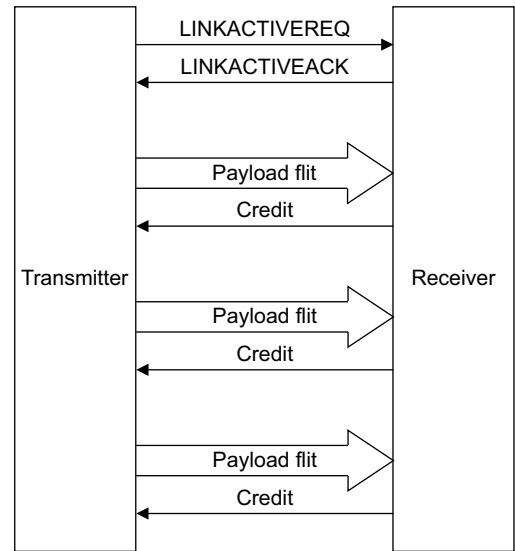

Figure 14-4 Example of a multiple channel unidirectional interface

The rules regarding the relationship between the **LINKACTIVEREQ** and **LINKACTIVEACK** signals must be applied appropriately across all channels:

- When a state change requires the Transmitter to be able to accept credits, it must be able to accept credits on all channels.
- When a state change requires the Receiver to be able to accept flits, it must be able to accept flits on all channels.
- When the sending of flits must stop before a state change, the sending of flits must stop on all channels.
- When the sending of credits must stop before a state change, the sending of credits must stop on all channels.
- A credit can only be associated with a flit on the same channel.

14.6 Transmit and receive link Interaction

This section describes the interaction between a link Transmitter and Receiver. It contains the following subsections:

- [Introduction](#)
- [Tx and Rx state machines](#) on page 14-463
- [Expected transitions](#) on page 14-465

14.6.1 Introduction

A single component has various different channels, some of which are inputs and some of which are outputs.

For a single component:

- All the channels where the Payload is an output are defined to be the *Transmit Link* (TXLINK).
- All the channels where the Payload is an input are defined to be the *Receive Link* (RXLINK).

It is required that the activation and deactivation of the TXLINK and RXLINK are coordinated.

When the TXLINK and RXLINK are both in the stable STOP state:

- If the RXLINK moves to the ACTIVATE state, which is controlled by the component on the other side of the interface, it is required that the TXLINK also moves to the ACTIVATE state, in a timely manner.
- If a component moves the TXLINK to the ACTIVATE state, which it controls, it can expect the RXLINK to also move to the ACTIVATE state, in a timely manner.

When the TXLINK and RXLINK are both in the stable RUN state:

- If the RXLINK moves to the DEACTIVATE state, which is controlled by the component on the other side of the interface, it is required that the TXLINK also moves to the DEACTIVATE state, in a timely manner.
- If a component moves the TXLINK to the DEACTIVATE state, which it controls, it can expect the RXLINK to also move to the DEACTIVATE state, in a timely manner.

When the TXLINK and RXLINK are changing states, the rules about the sending and receiving of credits and flits can be considered independently for each link.

14.6.2 Tx and Rx state machines

Figure 14-5 shows the permitted relationships between the Tx and Rx state machines. It is formatted so that the independent nature of the Tx and Rx state machines can be seen.

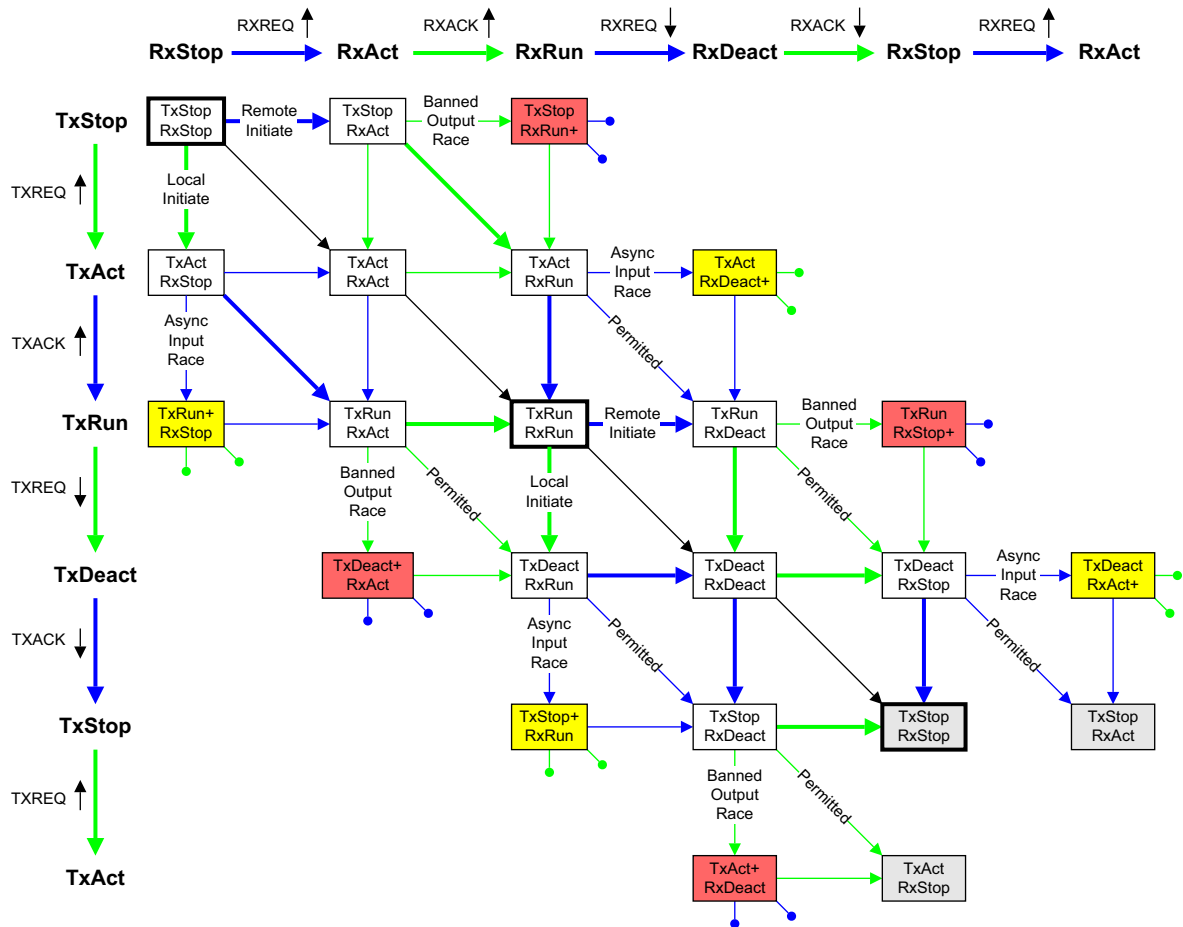

Figure 14-5 Combined Tx and Rx state machines

Figure 14-5 shows the combined Tx and Rx state machines for a single component:

- For clarity, shortened state names and signal names are used.
- A green arrow represents a transition that the local agent can control.
- A blue arrow represents a transition that is under the control of the remote agent on the other side of the interface.
- A black arrow represents a transition that is made when both the local and remote agents make a transition at the same time.
- Around the edge of Figure 14-5 is an indication of the individual Tx and Rx states. The green and blue arrows show which agent controls the transition. There is also an indication of the signal change that causes the state transition.
- A vertical or horizontal arrow is a state change caused by just one signal change, that is, only the Rx state machine or the Tx state machine changes state, not both.
- A diagonal arrow is a state change caused by two signals changing at the same time. If the diagonal arrow is green or blue, the same agent is changing both signals.

- There are a few cases where, by coincidence, a state change occurs due to two events, one on each side of the link, occurring at the same time. This is always a diagonal path and is shown by a black arrow.
- The stub-lines show dead-end paths where an exit from a state is not permitted. The color of a stub-line indicates which agent is responsible for ensuring that the path is not taken.
- The TxStop/RxStop and TxRun/RxRun states are expected to be stable states, and are typically the states where the state machines stay for long periods of time. These states are highlighted with a bold outline. All other states are considered transient states that are exited in a timely manner.
- The gray states, on the bottom right of [Figure 14-5 on page 14-463](#), are replications of those on the top left. They are shown to aid clarity and maintain the symmetry of the diagram.
- The yellow states can only be reached by observing a race between two input signals. The transition into these states is labeled with *Async Input Race*. See [Asynchronous race condition on page 14-466](#).
- The red states can only be reached by observing a race between two output signals. A race between two outputs is not permitted at the edge of a component and therefore the transition into these states is labeled with *Banned Output Race*. These states can only be observed at a midpoint between two components. See [Asynchronous race condition on page 14-466](#).
- The bold arrows are used to indicate the expected transitions around the state machine. These are described in more detail in [Expected transitions on page 14-465](#).
- The arrows labeled *Permitted* are state transactions that would not normally be expected, but they are permitted by the protocol.

State naming

[Figure 14-5 on page 14-463](#) shows the full set of states, including those that can only be reached through race conditions. A more detailed discussion of race conditions can be found in [Asynchronous race condition on page 14-466](#).

There are two different TxStop/RxRun states and two different TxRun/RxStop states. These states differ in how they are reached and how it is permitted to exit from them. To differentiate between these states, a [+] suffix is used to indicate which state machine, Tx or Rx, is running ahead. For example:

- TxStop/RxRun+ indicates that the Tx state machine has remained in the previous STOP state, while the Rx state machine has advanced to the next RUN state.
- TxStop+/RxRun indicates that the Tx state machine has advanced to the next STOP state, while the Rx state machine remains in the previous RUN state.

14.6.3 Expected transitions

Figure 14-6 shows the expected state transitions.

Figure 14-6 Expected Tx and Rx state machines transitions

Figure 14-6 shows, using bold arrows, the routes between the stable TxStop/RxStop and TxRun/RxRun states, and between the stable TxRun/RxRun and the TxStop/RxStop states.

The difference between the two routes moving from TxStop/RxStop to TxRun/RxRun states compared to moving from TxRun/RxRun to TxStop/RxStop states is due to the requirement to return L-Credits in the latter case. The differences are detailed in the following sections.

Expected transitions from TxStop/RxStop to TxRun/RxRun

There are two expected routes from a stable Stop/Stop to Run/Run state. Table 14-4 shows, in terms of the state transitions, the two expected paths.

Table 14-4 Stop/Stop to Run/Run state paths

Route	State 1	State 2	State 3	State 4
Path 1	TxStop/RxStop	TxStop/RxAct	TxAct/RxRun	TxRun/RxRun
Path 2	TxStop/RxStop	TxAct/RxStop	TxRun/RxAct	TxRun/RxRun

The annotations on the diagram arrows in [Figure 14-6 on page 14-465](#) are:

Local Initiate	Indicates that the local agent has initiated the process of leaving one stable state towards the other stable state.
Remote Initiate	Indicates that the remote agent on the other side of the interface has initiated the process of leaving one stable state towards the other stable state.

Expected transitions from TxRun/RxRun to TxStop/RxStop

A transition from a Run/Run state to a Stop/Stop state requires that L-Credits are returned. A link must remain in the DEACTIVATE state until all L-Credits are returned.

There are four expected routes from a stable Run/Run to Stop/Stop state. [Table 14-5](#) shows, in terms of the state transitions, the four expected paths.

Table 14-5 State 5

Route	State 1	State 2	State 3	State 4	State 5
Path 1	TxRun/RxRun	TxDeact/RxRun	TxDeact/RxDeact	TxStop/RxDeact	TxStop/RxStop
Path 2	TxRun/RxRun	TxDeact/RxRun	TxDeact/RxDeact	TxDeact/RxStop	TxStop/RxStop
Path 3	TxRun/RxRun	TxRun/RxDeact	TxDeact/RxDeact	TxStop/RxDeact	TxStop/RxStop
Path 4	TxRun/RxRun	TxRun/RxDeact	TxDeact/RxDeact	TxDeact/RxStop	TxStop/RxStop

Transitioning around a stable state

It is permitted, but not expected, to transition around a stable TxRun/RxRun or TxStop/RxStop state.

In the majority of cases, moving to the stable Run/Run or Stop/Stop state would be expected.

The most likely use case for wanting to move quickly out of one of the stable states is when an interface has started to enter a low power state, but there is still some activity required. It might be that the low power state was entered prematurely, or it might be that some new activity arose, by coincidence, while the low power state was being entered. In this use case, it is desirable to be able to move back to the Run/Run state as quickly as possible.

Asynchronous race condition

There are situations where two output signals, X and Y, have a defined relationship such that:

- Output X must change after or at the same time as output Y, but it is not permitted to change before output Y.

This relationship applies specifically as follows:

- The assertion of RXACK must not occur before the assertion of TXREQ.
- The deassertion of RXACK must not occur before the deassertion of TXREQ.
- The assertion of TXREQ must not occur before the deassertion of RXACK.
- The deassertion of TXREQ must not occur before the assertion of RXACK.

In [Figure 14-5 on page 14-463](#), these transitions are labeled as ‘Banned Output Race’ and the resultant state is shown in red.

It is possible to observe these states if monitoring the output signals at a point in the system where asynchronous race conditions can result in two signals, that are asserted within the same cycle, are observed in different clock cycles.

A component that is on the other side of the interface, and has the two signals as inputs, can see the state transition if an asynchronous input race occurs. These transitions are labeled on the diagram as ‘Aysnc Input Race’ and the resultant state is shown in yellow.

For all input race conditions, a component that observes the input race is required to wait for both signals before changing any output signals. This is represented in Figure 14-5 on page 14-463 by the fact that the only permitted output transition from a race state is caused by the arrival of the other signal associated with the race condition.

Combined Tx and Rx state machines without race conditions

In Figure 14-7, all transitions and states that occur as a result of a race condition in the combined Tx and Rx state machines have been removed.

Figure 14-7 Combined Tx and Rx state machines without race conditions

14.7 Protocol layer activity indication

This section describes the signals that indicate Protocol layer activity. It contains the following subsections:

- [Introduction](#)
- [TXSACTIVE signal](#)
- [RXSACTIVE signal on page 14-470](#)
- [Relationship between SACTIVE and LINKACTIVE on page 14-471](#)

14.7.1 Introduction

SACTIVE signaling indicates that there are transactions in progress.

TXSACTIVE is an output signal that is asserted by an interface where there is a transaction either in progress or about to start:

- **TXSACTIVE** must be asserted before or in the same cycle in which the first flit relating to a transaction is sent.
- **TXSACTIVE** must remain asserted until after the last flit relating to all transactions is sent or received.

This means that the deassertion of **TXSACTIVE** on an interface implies that the component has completed all transactions in progress and does not need to send or receive any further flits.

A transaction that is given a RetryAck response is considered to be in progress, **TXSACTIVE** must remain asserted until the associated credit has been supplied and used or returned.

RXSACTIVE is an input signal which indicates that the other side of the interface has ongoing Protocol layer activity. When **RXSACTIVE** is asserted, a component must respond to Protocol layer activity in a timely manner.

SACTIVE signals must be synchronous to **CLK** and therefore are not required to be synchronized. If they cross a clock domain, the clock domain crossing bridge is required to synchronize the signals.

14.7.2 TXSACTIVE signal

The following rules apply to the **TXSACTIVE** signal:

- **TXSACTIVE** must be asserted when the transmitter has flits to send.
- A component that asserts **TXSACTIVE** must also, if required, initiate the link activation sequence. It is not permitted for a component to assert the **TXSACTIVE** signal and then wait for the other side of the interface to initiate the link activation sequence.
- **TXSACTIVE** must remain asserted until after the last flit relating to all transactions is sent or received.
- It is permitted, but not required, for **TXSACTIVE** to be deasserted while transmitting link flits as part of the link deactivation sequence.

———— Note ————

To ensure an efficient power down sequence, it is recommended not to assert a deasserted **TXSACTIVE** signal during a link deactivation sequence.

It is permitted, but not required, for the interface on an interconnect component to use the **RXSACTIVE** input signal to directly generate the **TXSACTIVE** output signal. This behavior is only permitted on the interconnect interface and it is not permitted on any attached component.

Except for an interconnect interface of a Link, no other interface of a Link is permitted to loop-back the incoming **RXSACTIVE** onto the outgoing **TXSACTIVE**.

[Figure 14-8 on page 14-469](#) shows the requirements for **TXSACTIVE** assertion during the life of a transaction.

Figure 14-8 TXSACTIVE assertion during the life of a transaction

TXSACTIVE signaling from a Request Node

When initiating new transactions, a Request Node must assert **TXSACTIVE** in the same cycle or before **TXREQFLITV** is asserted and must keep it asserted until after the final completing flit of a transaction is sent or received.

The type of flit that completes a transaction initiated by a Request Node depends on both the transaction type and the manner in which the transaction progresses. For example, a ReadNoSnp transaction might typically complete with the receipt of the last CompData flit, but could equally complete with a ReadReceipt, if this is later than the last CompData flit.

An RN-F or RN-D component must also assert **TXSACTIVE** while a Snoop transaction is in progress. **TXSACTIVE** must be asserted after receiving an initiating snoop or SnpDVMOp flit, and no later than when its first Response flit is sent. It must keep **TXSACTIVE** asserted until after the final completing flit is sent for all Snoop transactions. The lifetime of a PrefetchTgt is a single flit. For the PrefetchTgt, the initiating flit is also the completing flit and the transaction can be considered complete in the following cycle after it is sent from the perspective of **TXSACTIVE**.

For an RN-F or RN-D, the **TXSACTIVE** output is the logical OR of the requirements for the Request interface and the Snoop interface.

TXSACTIVE signaling from a Subordinate Node

A Subordinate Node cannot initiate new transactions and is only required to assert **TXSACTIVE** while it is processing a transaction that is in progress.

It must assert **TXSACTIVE** after receiving a transaction initiating flit and it must be asserted before or in the same cycle in which its first Response flit is sent. It must keep **TXSACTIVE** asserted until after the final completing flit is sent or received.

TXSACTIVE signaling from an interconnect interface to a Request Node

The interconnect interface to a Request Node must assert **TXSACTIVE** in both the following conditions:

- On receiving a transaction initiating flit, it must be asserted before or in the same cycle in which its first Response flit is sent. It must keep **TXSACTIVE** asserted until after the final completing flit is sent or received.
- Before or in the same cycle in which its initiating Snoop or SnpDVMOp flit is sent. It must keep **TXSACTIVE** asserted until after the final completing flit is sent, which will be either SnpResp or SnpRespData.

TXSACTIVE signaling from an interconnect interface to a Subordinate Node

The interconnect interface to a Subordinate Node must assert **TXSACTIVE** before or in the same cycle in which its initiating Request flit is sent. It must keep **TXSACTIVE** asserted until after the final completing flit is sent or received.

14.7.3 RXSACTIVE signal

When **RXSACTIVE** is asserted, the receiver must respond to a link activation request in a timely manner. It is permitted for a Receiver to delay responding to a Link activation request when **RXSACTIVE** is deasserted.

———— **Note** ————

The deassertion of **RXSACTIVE** does not indicate that all Protocol layer activity has completed. It is possible for a Receiver to receive a Protocol flit, which corresponds to a transaction that was in progress while **RXSACTIVE** was asserted, after **RXSACTIVE** is deasserted.

RXSACTIVE can be used in combination with a knowledge of the ongoing transactions, which will be indicated by the components **TXSACTIVE** output, to indicate that no further transactions are required. This can be used to control entry to a low power state.

14.7.4 Relationship between **SACTIVE** and **LINKACTIVE**

SACTIVE signaling is an indication of Protocol layer activity. A node can be considered inactive when both **TXSACTIVE** and **RXSACTIVE** are deasserted.

LINKACTIVE state is an indication of the Link layer activity. The Link layer at a node, or interconnect, can be considered inactive when its Transmitter is in TxStop state and its Receiver is in RxStop state.

SACTIVE signaling is orthogonal to the **LINKACTIVE** states with one constraint as specified in [RXSACTIVE signal on page 14-470](#).

A node, or interconnect, should only enable higher-level clock gating and low power optimizations when both its Protocol and Link layers are inactive.

Chapter 15

System Coherency Interface

This chapter describes the interface signals that support connecting and disconnecting an RN-F from both the Coherency and DVM domains and an RN-D from the DVM domain. It contains the following sections:

- [Overview on page 15-474](#)
- [Handshake on page 15-475](#)

15.1 Overview

The system coherency interface signals are:

SYSCOREQ Requester coherency request.

SYSCOACK Interconnect coherency acknowledge.

Both **SYSCOREQ** and **SYSCOACK** signals must be synchronous to **CLK** and therefore are not required to be synchronized. If they cross a clock domain, the clock domain crossing bridge is required to synchronize the signals.

Figure 15-1 shows the system coherency interface signals connections.

Figure 15-1 System coherency interface signals

———— **Note** ————

In this chapter:

- Coherency when stated, includes the DVM domain, unless explicitly stated otherwise.
- Snoop when stated, includes SnpDVMOp, unless explicitly stated otherwise.

15.2 Handshake

A Request Node, an RN-F or an RN-D, requests connection to system coherency by setting **SYSCOREQ** HIGH. The interconnect indicates that coherency is enabled by setting **SYSCOACK** HIGH.

The Request Node requests disconnection from system coherency by setting **SYSCOREQ** LOW. The interconnect indicates that coherency is disabled by setting **SYSCOACK** LOW.

Requests to enter and exit coherency are always initiated by the Request Node.

Figure 15-2 shows the system coherency interface handshake timing.

Figure 15-2 System coherency interface handshake timing

As Figure 15-2 shows, the interface signaling obeys four-phase handshake rules:

- **SYSCOREQ** can only change when **SYSCOACK** is at the same logic state.
- **SYSCOACK** can only change when **SYSCOREQ** is at the opposite logic state.

15.2.1 RN rules

Referring to Figure 15-2, a Request Node must:

- Be able to service Snoop requests when it sets **SYSCOREQ** HIGH at **t1**.
- Not issue a transaction that permits it to cache a coherent location until **SYSCOACK** goes HIGH at **t2**.
- Ensure all transactions that permit it to cache a coherent location are complete before it sets **SYSCOREQ** LOW at **t3**.

SYSCOREQ can only be deasserted on the cycle after all of the following:

- All data packets are received for Reads.
- All data packets are sent for CopyBack.
- All data packets are sent for snoops and Forwarding snoops.
- Comp is received for Dataless transactions.

- Keep servicing Snoop requests until **SYSCOACK** is sampled LOW at **t4**.

SACTIVE must be asserted during coherency connect transition periods to guarantee the **SYSCOACK** transition occurs. See [Protocol layer activity indication on page 14-468](#).

———— Note ————

The transactions that permit a coherent location to be cached are:

- ReadUnique
- ReadPreferUnique
- MakeReadUnique
- ReadClean
- ReadNotSharedDirty
- ReadShared
- CleanUnique
- MakeUnique

15.2.2 Interconnect rules

Referring to [Figure 15-2 on page 15-475](#):

When the interconnect samples **SYSCOREQ** HIGH it must:

- Set **SYSCOACK** HIGH without waiting for responses to any Snoop requests that it has sent after **SYSCOREQ** goes HIGH.
- Be able to service coherent data accesses from the interface when it sets **SYSCOACK** HIGH at **t2**.

When the interconnect samples **SYSCOREQ** LOW it must:

- Complete all snoop accesses to the interface before it sets **SYSCOACK** LOW at **t4**.

15.2.3 Protocol states

[Table 15-1](#) shows the interface states and the rules that the Requester must follow in relation to the interface state.

Table 15-1 System coherency interface states

State name	SYSCOREQ	SYSCOACK	Description
Coherency Disabled	0	0	<ul style="list-style-type: none"> • RN caches must not contain coherent data. • RN must not issue transactions that permit it to cache a coherent location or send DVM transactions. • RN not required to respond to Snoop requests. • Interconnect must not send Snoop requests.
Coherency Connect	1	0	<ul style="list-style-type: none"> • RN caches must not contain coherent data. • RN must not issue transactions that permit it to cache a coherent location or send DVM transactions. • RN must respond to Snoop requests. • Interconnect can send Snoop requests.
Coherency Enabled	1	1	<ul style="list-style-type: none"> • RN caches can contain coherent data. • RN can issue transactions that cache a coherent location and send DVM transactions. • RN must respond to Snoop requests.
Coherency Disconnect	0	1	<ul style="list-style-type: none"> • RN caches must not contain coherent data. • RN must not issue transactions that permit it to cache a coherent location or send DVM transactions. • RN must respond to Snoop requests. • Interconnect must complete outstanding Snoop requests but must not generate new Snoop requests.

Chapter 16

Properties, Parameters, and Broadcast Signals

This chapter describes the properties, parameters, and optional broadcast signals that specify the behavior supported by an interface. It contains the following sections:

- [*Interface properties and parameters on page 16-478*](#)
- [*Optional interface broadcast signals on page 16-482*](#)
- [*Atomic transaction support on page 16-486*](#)

16.1 Interface properties and parameters

A property is used to declare a capability. If a property is not declared, it is considered False.

The properties and parameters that specify the interface behavior are described in the following sections:

- [Atomic_Transactions](#)
- [Cache_Stash_Transactions](#)
- [Direct_Memory_Transfer](#)
- [Data_Poison](#)
- [Direct_Cache_Transfer](#) on page 16-479
- [Data_Check](#) on page 16-479
- [Check_Type](#) on page 16-479
- [CleanSharedPersistSep_Request](#) on page 16-479
- [MPAM_Support](#) on page 16-479
- [CCF_Wrap_Order](#) on page 16-480
- [Req_Addr_Width](#) on page 16-480
- [NodeID_Width](#) on page 16-480
- [Data_Width](#) on page 16-480
- [Enhanced_Features](#) on page 16-480
- [DVM_Support](#) on page 16-480

16.1.1 Atomic_Transactions

An Atomic_Transactions property is used to indicate if a component supports Atomic transactions:

- When not specified, or set to False, Atomic transactions are not supported.
- When set to True, Atomic transactions are supported.

A component that supports Atomic transactions must support all Atomic transactions. However, it is not required that a component that supports Atomic transactions supports the targeting of all memory types.

16.1.2 Cache_Stash_Transactions

A Cache_Stash_Transactions property is used to indicate if a component supports Cache Stashing transactions:

- When not specified, or set to False, Cache Stashing transactions are not supported.
- When set to True, Cache Stashing Transactions are supported.

16.1.3 Direct_Memory_Transfer

A Direct_Memory_Transfer property is used to indicate if a component supports Direct Memory Transfer transactions:

- When not specified, or set to False, Direct Memory Transfer transactions are not supported.
- When set to True, Direct Memory Transfer transactions are supported.
- The Direct_Memory_Transfer property is defined at each HN for each SN.

16.1.4 Data_Poison

A Data_Poison property is used to indicate if a component supports Poison:

- When not specified, or set to False, Poison is not supported and the Poison field is not present in the DAT packet.
- When set to True, Poison is supported and the Poison field is present in the DAT packet.

See [Poison](#) on page 9-355.

16.1.5 Direct_Cache_Transfer

A Direct_Cache_Transfer property is used to indicate if a component supports Direct Cache Transfer transactions:

- When not specified, or set to False, Direct Cache Transfer transactions are not supported.
- When set to True, Direct Cache Transfer transactions are supported.
- It is the responsibility of the HN-F to determine the correct snoop type to use.

16.1.6 Data_Check

The Data_Check property is used to indicate the DataCheck field is present in the DAT packet:

- When not specified, or set to False, the DataCheck field is not in the DAT packet unless specified by the Check_Type property.
- When set to Odd_Parity, Data Check is supported and the DataCheck field is present in the DAT packet. If Check_Type is defined and set to Odd_Parity_Byte_All, no DataCheck field is present in the DAT packet.

See [Data Check on page 9-356](#).

16.1.7 Check_Type

The Check_Type property is used to indicate the protection scheme employed on an interface:

- When not specified, or set to False, no checking signals are present on the interface, unless specified by the Data_Check property.
- When set to Odd_Parity_Byte_Data, the DataCheck field is present in the DAT packet.
- When set to Odd_Parity_Byte_All, parity check signals are added to every channel. The signals added are detailed in [Interface parity check signals on page 9-359](#).

16.1.8 CleanSharedPersistSep_Request

The CleanSharedPersistSep_Request property is used to indicate if a component supports CleanSharedPersistSep:

- When not specified, or set to False, the component does not support CleanSharedPersistSep and the component must not be sent a CleanSharedPersistSep request.
- When set to True, the component supports CleanSharedPersistSep.
- A Home that receives a CleanSharedPersistSep request must support such a request.
- A Home can track if a connected Subordinate supports CleanSharedPersistSep.
- If a Subordinate does not support CleanSharedPersistSep:
 - The Home must send a CleanSharedPersist instead of a CleanSharedPersistSep request to that Subordinate.
 - Home must take the responsibility of sending the Persist response to the Requester. This Persist response must only be sent after receiving the Comp response from the Subordinate.
- A Requester that does not support CleanSharedPersistSep will generate CleanSharedPersist instead.

16.1.9 MPAM_Support

The MPAM_Support property is used to indicate whether an interface supports MPAM.

- When not specified, or set to False, MPAM is not supported:
 - The interface is not MPAM enabled.
 - No MPAM fields are present on the interface.

- When set to MPAM_9_1, the interface is enabled for partitioning and monitoring:
 - It must include the MPAM field on the REQ, DAT, and SNP channels.
 - The width of PartID is 9 bits and the width of PerfMonGroup is 1 bit.

How the MPAM field values are used by a receiver is IMPLEMENTATION DEFINED.

16.1.10 CCF_Wrap_Order

See *Critical chunk first wrap order* on page 2-148.

16.1.11 Req_Addr_Width

This parameter specifies the maximum physical address supported by a component:

- Legal values for this parameter are 44 to 52.
- When Req_Addr_Width is not specified, the default value is 44.

16.1.12 NodeID_Width

This parameter specifies the width of NodeID fields supported by a component, which determines the maximum permitted NodeID value in the system:

- The width specified is uniformly applied to all NodeID related fields.
- Legal values of NodeID_Width are 7 to 11.
- When NodeID_Width is not specified, the default value is 7.

16.1.13 Data_Width

This parameter specifies the data width in the DAT channel packet supported by a component:

- Legal values for Data_Width are 128, 256, and 512.
- When Data_Width is not specified, the default value is 128.

16.1.14 Enhanced_Features

The Enhanced_Features property describes the combined support for some of the miscellaneous features in the CHI specification that do not have an explicit property or parameter defined.

When the Enhanced_Features property is True, the component supports all the following enhanced features:

- Data return from SC state.
- I/O Deallocation transactions.
- ReadNotSharedDirty transaction.
- CleanSharedPersist transaction.
- Receiving of Forwarding snoops.

When not specified, or set to False, the component does not support the enhanced features that do not have an explicitly defined property or parameter.

16.1.15 DVM_Support

A DVM_Support property is used to indicate Arm ARM specification supported by a given component. When set to:

- | | |
|-----------------|--|
| False | The component does not support any DVM transactions. |
| DVM_v8 | The component supports DVM transactions required to support Armv8. |
| DVM_v8.1 | The component supports DVM transactions required to support Armv8.1. |
| DVM_v8.4 | The component supports DVM transactions required to support Armv8.4. |

In a system with heterogeneous components, it is the responsibility of the system configuration to determine the lowest common DVM specification supported in the system. The interconnect must have the knowledge of this lowest common denominator value by means of configuration, straps, parameterization, or some other IMPLEMENTATION DEFINED method.

To avoid deadlocks and denial of service, the interconnect must detect unsupported DVM operations. The interconnect must suppress unsupported DVM operation propagation and respond in a protocol-compliant manner. Error indication in such a response is optional.

———— **Note** ————

The following expression can be used by the interconnect to determine if a DVM operation is a new one added in Armv8.4 and not supported by older specifications.

If the following expression is true, then the transaction is a DVM operation supported by Armv8.4 only.

[TLBI and (
 (Hypervisor and Secure) or
 (Guest OS and Secure and VMID) or
 (Non-secure only) or
 (Range))] OR
[VICI and (
 (Guest OS and Secure and VMID))]

16.2 Optional interface broadcast signals

This specification includes six sets of optional pins to determine broadcasting of certain groups of transactions in the interconnect. These pins are optional at the Request Node to the interconnect, and the interconnect to the Subordinate Node interfaces. The optional broadcast pins are:

- [BROADCASTINNER and BROADCASTOUTER](#)
- [BROADCASTCACHEMAINTENANCE](#)
- [BROADCASTPERSIST](#)
- [BROADCASTATOMIC](#) on page 16-484
- [BROADCASTICINVAL](#) on page 16-484
- [BROADCASTMTE](#) on page 16-484
- [BROADCASTERTLBIINNER and BROADCASTTLBIOUTER](#) on page 16-484

An implementation that includes these signals at the interface must ensure that the signal values are stable when Reset is deasserted.

16.2.1 BROADCASTINNER and BROADCASTOUTER

The **BROADCASTINNER** and **BROADCASTOUTER** signals are used to control the issuing of Non-snoopable transactions from an interface. It is required that these two pins must be set to the same value.

When the signals are present and deasserted, all transactions are converted to Non-snoopable equivalents before they are sent. The transaction conversion from Snoopable to Non-snoopable, using the **BROADCASTINNER** and **BROADCASTOUTER** signals, the following conversions apply:

- All Read transactions must be converted to ReadNoSnp.
- All Snoopable CMO transactions must be converted to Non-snoopable CMO.
- The following Dataless transactions must be dropped:
 - CleanUnique
 - MakeUnique
 - Evict
 - StashOnce
 - StashOnce*Unique
 - StashOnce*Shared
- All Combined Writes must be converted to Combined WriteNoSnp.
- All Write transactions, except WriteEvictFull and WriteEvictOrEvict, must be converted to WriteNoSnp.
- WriteEvictFull and WriteEvictOrEvict transactions must be dropped.
- All Snoopable Atomic transactions must be converted to Non-snoopable.
- PrefetchTgt transaction conversion is not required.

16.2.2 BROADCASTCACHEMAINTENANCE

The **BROADCASTCACHEMAINTENANCE** signal is used to control the issuing of cache maintenance operations when there are no software-managed caches downstream of the interface.

When the **BROADCASTCACHEMAINTENANCE**, **BROADCASTINNER**, and **BROADCASTOUTER** signals are all present and deasserted:

- CleanShared, CleanInvalid, and MakeInvalid transactions are not issued.
- All Combined Write transactions must be converted to standalone Write transactions.

16.2.3 BROADCASTPERSIST

The **BROADCASTPERSIST** signal is used to control the issuing of CleanSharedPersist and CleanSharedPersistSep Cache Maintenance Operations.

When the **BROADCASTPERSIST** signal is present and deasserted, CleanSharedPersist and CleanSharedPersistSep transactions are converted to CleanShared. The conversion applies to both standalone CMO and Combined Write transactions.

———— **Note** —————

The issuing of the CleanShared is controlled by the **BROADCASTINNER**, **BROADCASTOUTER**, and **BROADCASTCACHEMAINTENANCE** signals.

—————

16.2.4 BROADCASTATOMIC

The **BROADCASTATOMIC** signal is used to control the generation of Atomic transactions:

- When asserted, the interface is permitted, but not required, to generate Atomic transactions.
- When deasserted, the interface must not generate Atomic transactions.

A Request Node is not required to make use of Atomic transactions. A Request Node that does not make use of Atomic transactions itself, needs no added functionality to be compatible with an interconnect that supports Atomic transactions.

A Request Node that supports atomic operations but does not include support for the execution of atomic operations must be able to send Atomic transactions.

See [Atomic transaction support on page 16-486](#).

16.2.5 BROADCASTICINVAL

The **BROADCASTICINVAL** signal at each Request Node is used to inform the Request Node that broadcasting of *Instruction Cache* (ICache) invalidations using the DVM mechanism is required:

- When asserted, DVMOp for ICache Invalidation must be sent to the interconnect.
- When deasserted, DVMOp for ICache invalidations are not required to be sent to the interconnect.

In a system where all Instruction Caches are fully coherent the hardware coherency mechanism automatically invalidates all ICache copies on a cache line update. In such systems, it is not necessary to broadcast ICache invalidation operations.

If a system contains one or more Instruction Caches that are not updated by the hardware coherency mechanism, then it is necessary for ICache invalidation operations to be broadcast using DVM transactions.

16.2.6 BROADCASTMTE

The **BROADCASTMTE** signal is used to control the issuing of requests with MTE beyond the interface:

- When asserted, requests with MTE can be sent beyond the interface.
- When deasserted, requests with MTE must not be sent beyond the interface.

The **BROADCASTMTE** signal is typically deasserted when the interface does not support MTE functionality.

When the **BROADCASTMTE** signal is deasserted, all other MTE-related interface pins must be tied to zero. The interconnect is permitted, but not required, to remove the related MTE transport wires.

The interface fields that can be fixed to a value of zero are:

- On DAT channels:
 - TagOp, Tag, and TU
- On REQ and RSP channels:
 - TagOp

16.2.7 BROADCASTERTLBIINNER and BROADCASTTLBIOUTER

The **BROADCASTTLBIINNER** (BTI) and **BROADCASTTLBIOUTER** (BTO) signals are used to control the issuing of TLBI operations in the interconnect.

Table 16-1 shows the permitted **BTI** and **BTO** signal encodings.

Table 16-1 BTI and BTO signal encodings

BTI	BTO	Permitted
0	0	Yes
0	1	Yes
1	0	Reserved
1	1	Yes

Note

The decision to broadcast a DVM(Sync) does not only depend on the values of BTI and BTO but must also consider if any DVM operations other than TLBI must be pushed to their completion by the DVM(Sync).

16.3 Atomic transaction support

The CHI component support requirements for Atomic transactions are described in the following sections:

- [Request Node support](#)
- [Interconnect support on page 16-487](#)
- [Subordinate Node support on page 16-487](#)

16.3.1 Request Node support

A Requester component is required to support a mechanism to suppress the generation of Atomic transactions to ensure compatibility in systems where Atomic transactions are not supported. A Requester can use the optional interface pin **BROADCASTATOMIC** to determine whether Atomic transactions are transmitted.

A Request Node is not required to make use of Atomic transactions. A Request Node that does not use Atomic transactions itself needs no added functionality to be compatible with an interconnect that supports Atomic transactions.

A Request Node that supports atomic operations but does not include support for the execution of atomic operations must be able to send Atomic transactions.

For a Request Node that supports both the execution of atomic operations as well as the sending of Atomic transactions, the following applies:

For cacheable locations, both Snoopable and Non-snoopable, a Request Node is able to perform an atomic operation locally without generating an Atomic transaction at its interface. To achieve this, the Requester obtains a copy of the location in its local cache, in the same manner that it would for a store operation, and then performs the atomic operation within its local cache. For cacheable locations that are Snoopable, if the contents of the cache line are updated and the cache line was not previously Dirty, then the cache line must be marked as Dirty.

16.3.2 Interconnect support

Interconnect support for Atomic transactions is optional.

The `Atomic_Transactions` property is used to indicate that an interconnect supports Atomic transactions.

If Atomic transactions are not supported by the interconnect, all attached Request Nodes must be configured to not generate Atomic transactions. The **BROADCASTATOMIC** pin can be used for this purpose, when implemented. See [Request Node support on page 16-486](#).

For interconnects that support Atomic transactions, atomic operation execution can be supported at any point within an interconnect, including passing an Atomic transaction downstream to a Subordinate Node.

Atomic transactions are not required to be supported for every address location.

If Atomic transactions are supported for a given Snooperable address location, then they must be supported for the complete Snooperable address range.

If Atomic transactions are not supported for a given address location, then an appropriate Error response can be given for the Atomic transaction. See [Atomic transactions on page 9-350](#).

For transactions to a Device, the Atomic transaction must be passed to the appropriate endpoint Subordinate. If the Subordinate is configured to indicate that it does not support Atomic transactions, the interconnect must return an Error response for the transaction.

For Non-snooperable transactions, the Atomic transaction must be performed either:

- At a point, or past a point, where the transaction is visible to all other agents.
- At the endpoint.

For Snooperable transactions, the interconnect can either:

- Perform the atomic operation required by an Atomic transaction within the interconnect. This requires that the interconnect performs the appropriate Read, Write, and Snoop transactions to complete the Atomic transaction.
- If the appropriate endpoint Subordinate is configured to indicate that it supports Atomic transactions, the interconnect can pass the Atomic transaction to the Subordinate. The interconnect is still required to perform the appropriate Snoop and Write transactions before issuing the Atomic transaction to the Subordinate.

16.3.3 Subordinate Node support

Subordinate Node support for Atomic transactions is optional.

The `Atomic_Transaction` property is used to indicate that a Subordinate Node supports Atomic transactions.

If a Subordinate Node supports Atomic transactions for particular memory types, or for particular address regions, then on receiving an Atomic transaction that it does not support, the Subordinate Node must give an appropriate Error response.

Appendix A

Message Field Mappings

This appendix shows the field mappings for the request, response, data, and snoop request messages. It contains the following sections:

- [*Request message field mappings on page A-491*](#)
- [*Response message field mappings on page A-496*](#)
- [*Data message field mappings on page A-497*](#)
- [*Snoop Request message field mappings on page A-498*](#)

[Table A-1](#) shows the conventions used in the field mapping tables.

Table A-1 Key to field mapping table conventions

Symbol	Description
CF	Common Field. Two or more protocol message fields share the same set of bits in this packet field.
X	Inapplicable. Field value can take any value.
1	Applicable. Field value is used, must be set to one.
0	Applicable. Field value is used, must be set to zero.
0 ^a	Inapplicable. Field value must be set to zero.
Y	Applicable. Field value is used. See specification for permitted values and usage.
D	Inapplicable. Field value must be default setting for MPAM fields.
8B	Size field must be set to 8-byte encoding.
64B	Size field must be set to 64-byte encoding.
M	Field position reused for DVM operations. See Chapter 8 DVM Operations .
-	Assigned to another protocol message field that shares the same set of bits in this packet field.

A.1 Request message field mappings

Table A-2 and Table A-3 on page A-492 show the Read, Dataless and Miscellaneous Request message field mappings. See Table A-1 on page A-490 for the conventions used in the field mappings. For further information on field use see *Protocol flit fields* on page 13-424.

Appendix B

Communicating Nodes

This appendix specifies, for each packet type, the nodes that communicate using that packet type. It contains the following sections:

- [*Request communicating nodes*](#) on page B-500.
- [*Snoop communicating nodes*](#) on page B-502.
- [*Response communicating nodes*](#) on page B-503.
- [*Data communicating nodes*](#) on page B-504.

B.1 Request communicating nodes

Table B-1 shows the Request communicating nodes. In Table B-1, unless explicitly stated otherwise, a reference to a Write transaction includes both the individual Write transaction and the corresponding Combined Write transaction.

For some Requests, both an expected target and a permitted target are given. The use of the permitted target can occur in the case of a software based error. The permitted target must complete the transaction in a protocol compliant manner, this might require the use of an error response.

Table B-1 Request communicating nodes

B.4 Data communicating nodes

Table B-4 shows the Data communicating nodes.

For some Data, both an expected target and a permitted target are given. The use of the permitted target can occur in the case of an incorrect address decode. The permitted target must complete the transaction in a protocol compliant manner. In Table B-4, unless explicitly stated otherwise, a reference to a Write transaction includes both the individual Write transaction and the corresponding Combined Write transaction.

Table B-4 Data communicating nodes

Data		From	To	
			Expected	Permitted
Upstream	CompData	ICN(HN-F, HN-I)	RN-F, RN-D, RN-I	-

Appendix C

Revisions

This appendix describes the technical changes between released issues of this specification.

Table C-1 Issue B

Change	Location
No changes, first public release	—

Table C-2 Issue C

Change	Location
New feature: Response after receiving first Data packet.	Allocating Read on page 2-47. Non-allocating Read on page 2-50.
New feature: Separate Non-data and Data-only response.	Read transactions on page 2-47 and multiple related locations.
New feature: Combined CompAck with WriteData.	WriteUnique transaction on page 2-115 and multiple related locations.
Clarification: Regarding byte enables for Write transactions.	Byte Enables on page 2-143.
Update: Concerning the list of fields that can change value from the original request in the retried request.	Request Retry on page 2-154.
Clarification: Concerning the transaction responses permitted to be sent to the same address when a Snoop transaction response is pending.	At the RN-F node on page 4-253.

Table C-2 Issue C (continued)

Change	Location
Additional information: Concerning Legal RespErr field values for WriteDataCancel.	Table 9-7 on page 9-348.
Clarification: Regarding TraceTag field value propagation.	TraceTag usage and rules on page 11-376.
Corrections and additions: Concerning message field mappings.	Table A-3 on page A-492, Table A-8 on page A-496, and Table A-9 on page A-497.

Table C-3 Issue D

Change	Location
New feature: Persistent CMO with two part response.	Dataless transactions on page 2-80. Dataless transactions on page 2-109. Cache Maintenance transactions on page 4-181. Transaction identifier fields on page 2-93. Persistent CMO with snoop and separate Comp and Persist on page 5-268. Interface properties and parameters on page 16-478. Dataless transactions on page 9-347.
New feature: Deep Persistent cache maintenance.	Cache Maintenance transactions on page 4-181. Deep persistence, Deep on page 13-434.
New feature: Interface Parity.	Use of interface parity on page 9-357. Interface properties and parameters on page 16-478.
New feature: <i>Memory System Performance Resource Partitioning and Monitoring</i> (MPAM).	MPAM on page 11-373. Interface properties and parameters on page 16-478.
New feature: Completer Busy indication.	Completer Busy on page 11-375.
New feature: ICache Invalidation broadcast signal.	Optional interface broadcast signals on page 16-482.
Additional requirement: Concerning SACTIVE synchronization to CLK .	Protocol layer activity indication on page 14-468.
Additional requirement: Concerning SYSCOREQ and SYSCOACK synchronization to CLK .	Chapter 15 System Coherency Interface.
Correction: Concerning the use of RXSACTIVE to directly generate the TXSACTIVE signal.	TXSACTIVE signal on page 14-468.
Update: Concerning Ordered Write Observation flow enhancements.	Streaming Ordered Write transactions on page 2-129.
Update: Concerning the relaxation of the order requirement between Cache Maintenance transactions and any other transaction to the same address.	Cache Maintenance transactions on page 4-181.
Update: Concerning UD_PD state is permitted on a DataSepResp response.	Read and Atomic transaction completion on page 4-208.
Update: Concerning DVM early Comp.	DVM early Comp for Non-sync DVMOps on page 8-315.

Table C-3 Issue D (continued)

Change	Location
Update: Concerning increased TxnID width.	<i>Flit packet definitions on page 13-418.</i>
Clarification: Regarding when a RespSepData response includes a Non-data Error.	<i>Read transactions on page 9-345.</i>
Clarification: Regarding when the DataPull bit is set in a SnpRespData message.	<i>Data Pull, DataPull on page 13-441.</i>

Table C-4 Issue E.a

Change	Location
New feature: Writes with optional Data: <ul style="list-style-type: none"> WriteEvictOrEvict. 	<i>CopyBack Write on page 2-61.</i> <i>CopyBack transactions on page 4-188.</i> <i>Chapter 9 Error Handling.</i> <i>Chapter 12 Memory Tagging.</i>
New feature: Write Zero with no Data: <ul style="list-style-type: none"> WriteNoSnpZero. WriteUniqueZero. 	<i>Immediate write on page 2-55.</i> <i>Transaction ordering on page 2-125.</i> <i>Write transactions on page 4-187.</i> <i>Chapter 9 Error Handling.</i> <i>Chapter 12 Memory Tagging.</i>
New feature: SnpQuery Snoop request.	<i>Snoop request types on page 4-201.</i> <i>Chapter 9 Error Handling.</i>
New feature: DBIDRespOrd response.	<i>Immediate write on page 2-55.</i> <i>Miscellaneous response on page 4-218.</i>
New feature: New transactions to support Exclusive reads: <ul style="list-style-type: none"> ReadPreferUnique. SnpPreferUnique. SnpPreferUniqueFwd. MakeReadUnique. MakeReadUnique(Excl). 	<i>Read transactions on page 2-47.</i> <i>Stash transactions on page 2-76.</i> <i>Read transactions on page 4-173.</i> <i>Snoop request types on page 4-201.</i> <i>MakeReadUnique transaction on page 4-224.</i> <i>Exclusive transactions on page 6-296.</i> <i>MakeReadUnique(Excl) on page 6-298.</i> <i>Chapter 9 Error Handling.</i> <i>Chapter 12 Memory Tagging.</i>
New feature: Direct Write-data Transfer.	<i>Write Transactions on page 2-55.</i> <i>Do Direct Write Transfer, DoDWT on page 13-438.</i>
New feature: Combined Write transactions: <ul style="list-style-type: none"> CompCMO. 	<i>Transaction classification on page 1-27.</i> <i>Combined Immediate Write and CMO on page 2-62.</i> <i>Combined Write requests on page 4-192.</i>
New feature: Two-part StashOnce transaction including: <ul style="list-style-type: none"> StashOnceSep requests. StashDone response. CompStashDone response. 	<i>Stash transactions on page 2-76</i> <i>StashOnce or StashOnceSep transaction on page 2-117.</i> <i>Dataless transactions on page 4-180.</i> <i>Independent Stash request on page 7-307.</i> <i>Chapter 9 Error Handling.</i> <i>Chapter 12 Memory Tagging.</i>

Table C-4 Issue E.a (continued)

Change	Location
New feature: Forward indication on Snoop forward treated as a hint.	Request transactions and corresponding Snoop requests on page 4-204.
New feature: Increasing inter-port bandwidth: <ul style="list-style-type: none"> Multiple interfaces. Replicated channels. 	Increasing inter-port bandwidth on page 13-410.
New feature: Memory tagging.	Chapter 12 Memory Tagging.
New feature: Extending DVM operations: <ul style="list-style-type: none"> Range based TLBI. Level hint in TLBI operations, DVM Domain. 	Chapter 8 DVM Operations.
New feature: SLC replacement hint.	SLC replacement hint on page 11-371.
Additional requirement: Concerning Transaction Ordering guarantees.	Transaction ordering on page 2-125.
Additional requirement: Concerning change in WriteNoSnpFull behavior.	Write Transactions on page 2-55.
Correction: Concerning Size field value in ReadNoSnpSep.	Read transactions on page 4-173.
Correction: Concerning the Ordering guarantees provided by the Comp and CompData response.	Completion response and ordering on page 2-121.
Update: Concerning removal of the DoNotDataPull attribute on snoops.	-
Update: Concerning extending the GroupID field width.	See Table C-5 on page C-509 for further information.
Update: Concerning extending the TxnID field width.	Flit packet definitions on page 13-418.
Update: Concerning ICache invalidation operations.	Virtual Instruction Cache Invalidate on page 8-338.
Update: Concerning Secure EL2 TLBI operations.	TLB Invalidate on page 8-330.
Update: Concerning the Order requirements between transactions with different Order field values. ^a	Transaction ordering on page 2-125.
Clarification: Regarding Comp and cancelled Write.	Write Transactions on page 2-55.
Clarification: Regarding CopyBack Write transaction and RetryAck response.	Request Retry on page 2-154.
Clarification: Regarding the SnpAttr and Cacheable field value in a standalone CMO transaction.	Cache Maintenance transactions on page 4-181.
Clarification: Regarding the attributes of Exclusive accesses.	Exclusive monitors on page 6-293.
Clarification: Regarding the receiving of WriteData and the sending of the Persist response.	Cache Maintenance transactions on page 4-181.

a. This Update applies retroactively to CHI Issue D.

Table C-5 Issue E.b

Change	Location
Update: All offensive terminology has been replaced per Arm's commitment to progressive terminology.	Throughout the specification.
Update: Restructured and reformatted Transaction structures section.	Transaction structure on page 2-46
Clarification: SnpAttr bit reuse in DVMOp and inapplicability in PrefetchTgt.	Table 2-13 on page 2-140
Update: SLCRpHint value is permitted to be different in the resent request.	Request Retry on page 2-154
Clarification: Simultaneous pending of CMO and allocating requests to the same address.	Cache Maintenance transactions on page 4-181
Correction: Request Order permitted in WriteNoSnpZero from HN-I to SN-I.	Immediate Write transactions on page 4-187
Update: Re-write of transactions, grouping common characteristics.	Request types on page 4-172
Clarification: Permitted attribute values for requests, initial cache state at the Requester, and final cache state at the Requester outlined.	Request types on page 4-172
Correction: Order field value 0b00 and 0b01 permitted in ReadNoSnp ^a .	Read transactions on page 4-173
Correction: Security field 0b10 in PCI DVM operation expanded to include both Secure and Non-secure.	Table 8-5 on page 8-323
Clarification: Corrupt data must be marked with Poison, DERR, or NDERR.	Error response use by transaction type on page 9-345
Clarification: Poison on MTE is not supported.	Poison on page 9-355 Non-Tag Match errors on page 12-394
Correction: Legal RespErr field tables corrected.	Table 9-6 on page 9-348
Correction: Transaction error cannot be indicated in DBIDResp response.	Table 9-6 on page 9-348
Update: All four combinations of Request NS and MPAMNS field values are legal ^b .	MPAMNS on page 11-373
Clarification: MTE fields are inapplicable and must be set to zero in WriteDataCancel write data response.	TagOp, TU, and tags relationship on page 12-386
Update: Redundant GroupIDExt field definition is removed from the specification	Protocol flit fields on page 13-424
Clarification: Re-write of protocol flit fields.	Protocol flit fields on page 13-424
Correction: Requirements for DoNotGoToSD in SnpQuery updated.	Do not transition to SD state, DoNotGoToSD on page 13-442
Correction: Link deactivation and sending of protocol flits updated. Race conditions section deleted.	Table 14-3 on page 14-459
Clarification: Restructured and reformatted Broadcast signals.	Optional interface broadcast signals on page 16-482
Correction: TagGroupID field is applicable in WriteNoSnpPtl, WriteNoSnpFull, WriteUniquePtlStash, WriteUniqueFullStash, WriteUniquePtl, and WriteUniqueFull.	Table A-5 on page A-494

Table C-5 Issue E.b (continued)

Change	Location
Correction: PGroupID field applicable in WriteNoSnpPtl, WriteNoSnpFull, WriteUniquePtl, WriteUniqueFull, WriteCleanFull, and WriteBackFull.	Table A-5 on page A-494
Correction: Deep field in all CleanSharedPersist* and Write*CleanShPerSep requests applicable.	Table A-5 on page A-494
Correction: SLCTRepHint not applicable for Atomic transactions	Table A-7 on page A-495
Clarification: UniqueDirtyPartial cache line can have none, some, or all bytes valid.	Cache state model on page 1-32 and Cache line states on page 4-170
a. This correction is applied retrospectively to CHI Issue C, Issue D, and Issue E.a. b. This update is applied retrospectively to CHI Issue D and Issue E.a.	

Table C-6 Issue E.c

Change	Location
Editorial edits	Throughout the specification
Clarification: Cancellation of CopyBack requests following overlapping snoop	At the RN-F node on page 4-253 , Table 4-28 on page 4-211 , and Table 4-40 on page 4-230
Defect: ReadReceipt not optional in certain transaction flows	Figure 2-1 on page 2-48 and Table 2-6 on page 2-54
Clarification: DVM payload encoding for Instruction cache invalidations	Table 8-6 on page 8-325
Clarification: Typographical error in example WriteUniqueStash with Data Pull transaction flow	Figure 5-23 on page 5-280
Clarification: Requirements for ReadOnceMakeInvalid when invalidating a Dirty copy	Read transactions on page 4-173
Clarification: Requirements for Completer read response when MTE is not supported	MTE not supported on page 12-395
Clarification: Data_Check and Check_Type property descriptions	Data Check on page 9-356 , Data_Check on page 16-479 , and Check_Type on page 16-479
Clarification: Typographical error in Request Node to Home node request attribute values table	RN to HN Write request attribute values on page 4-189
Clarification: DBID value in Comp and DBIDResp messages that originate from different sources in DWT flow have no relationship	Data Buffer Identifier, DBID on page 2-94
Clarification: Field consistency requirements for data messages split into multiple packets	Data packetization on page 2-144

Glossary

This glossary describes some of the technical terms used in AMBA 5 CHI documentation.

Advanced Microcontroller Bus Architecture (AMBA)

The AMBA family of protocol specifications is the ARM open standard for on-chip buses. AMBA provides solutions for the interconnection and management of the functional blocks that make up a *System-on-Chip* (SoC). Applications include the development of embedded systems with one or more processors or signal processors and multiple peripherals.

Aligned

A data item stored at an address that is divisible by the highest power of 2 that divides into its size in bytes. Aligned halfwords, words, and doublewords therefore have addresses that are divisible by 2, 4, and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

AMBA

See [Advanced Microcontroller Bus Architecture \(AMBA\)](#).

At approximately the same time

Two events occur at approximately the same time if a remote observer might not be able to determine the order in which they occurred.

Barrier

An operation that forces a defined ordering of other actions.

Blocking

Describes an operation that prevents following actions from continuing until the operation completes.

A non-blocking operation can permit following operations to continue before it completes.

Byte

An 8-bit data item.

Cache

Any cache, buffer, or other storage structure that can hold a copy of the data value for a particular address location.

Cache hierarchy

The organization of different size caches in a hierarchy, typically with the cache with faster access and smaller size closer to the core and larger and slower access ones farther away from the core. The last level of this hierarchy might be connected to the memory. In this specification, in relation to a referenced cache, above refers to caches closer to the core, and below refers to caches farther from the core.

Cache line	<p>The basic unit of storage in a cache. Its size in words is always a power of two. A cache line must be aligned to the size of the cache line.</p> <p>The size of the cache line is equivalent to the coherency granule.</p> <p>See also Coherency granule.</p>
Cache state	<p>State of a block of data in a cache, of 64-byte size in this specification. The state determines if the block is cached in any other caches in the system and also if it is different from the copy of the block in memory. See Cache state model on page 1-32 for a description of the cache states supported in this specification.</p>
Channel	<p>A set of signals grouped together to communicate a particular set of messages between a transmitter and receiver pair. For example Request channel is used to communicate request messages.</p> <p>A channels consist of a set of information signals and a separate Valid and Credit signal to provide the channel handshake mechanism.</p>
Coherent	<p>Data accesses from a set of observers to a memory location are coherent accesses to that memory location by the members of the set of observers are consistent with there being a single total order of all writes to that memory location by all members of the set of observers.</p>
Coherency granule	<p>The minimum size of the block of memory affected by any coherency consideration. For example, an operation to make two copies of an address coherent makes the two copies of a block of memory coherent, where that block of memory is:</p> <ul style="list-style-type: none"> • At least the size of the coherency granule. • Aligned to the size of the coherency granule. <p>See also Cache line.</p>
Completer	<p>See Completer on page 1-25.</p>
Component	<p>A distinct functional unit that has at least one AMBA interface. Component can be used as a general term for Requester, Subordinate, peripheral, and interconnect components.</p> <p>See also Interconnect component, Requester component, Memory Subordinate component, Peripheral Subordinate component, Subordinate component.</p>
Deprecated	<p>Something that is present in the specification for backwards compatibility. Whenever possible you must avoid using deprecated features. These features might not be present in future versions of the specification.</p>
Device	<p>See Peripheral Subordinate component.</p>
Direct Data Transfer	<p>Sending Read data directly from a Snoopee or Subordinate to the Requester bypassing the Home Node.</p>
Downstream	<p>A transaction operates between a Requester component and one or more Subordinate components, and can pass through one or more intermediate components. At any intermediate component, for a given transaction, <i>downstream</i> means between that component and a destination Subordinate component, and includes the destination Subordinate component.</p> <p>Downstream and upstream are defined relative to the transaction as a whole, not relative to individual data flows within the transaction.</p> <p>See also Requester component, Peer to Peer, Subordinate component, Upstream.</p>
Downstream Cache	<p>See Downstream cache on page 1-24.</p>
Endpoint	<p>See Endpoint on page 1-25.</p>
Final Destination	<p>Final destination for a Memory transaction is a peripheral or physical memory, also called an Endpoint.</p>
Flit	<p>See Flit on page 1-24.</p>
HN	<p>See HN on page 1-25.</p>

ICN *See [ICN on page 1-25](#).*

In a timely manner *See [In a timely manner on page 1-26](#).*

IMPLEMENTATION DEFINED

Behavior that is not defined by the architecture, but is defined and documented by individual implementations.

When IMPLEMENTATION DEFINED appears in body text, it is always in small capitals.

IMPLEMENTATION SPECIFIC

Behavior that is not architecturally defined, and might not be documented by an individual implementation. Used when there are a number of implementation options available and the option chosen does not affect software compatibility.

When IMPLEMENTATION SPECIFIC appears in body text, it is always in small capitals.

Interconnect component

A component with more than one AMBA interface that connects one or more Requester components to one or more Subordinate components.

An interconnect component can be used to group together either:

- A set of Requesters so that they appear as a single Requester interface.
- A set of Subordinates so that they appear as a single Subordinate interface.

See also [Component](#), [Requester component](#), [Subordinate component](#).

IO Coherent node

See [IO Coherent node on page 1-26](#).

Line *See [Cache line](#).*

Link A Link is the connection used for communicating between a transmitter and receiver pair.

Link layer Credit *See [Link layer Credit on page 1-25](#).*

Load The action of a Requester component reading the value held at a particular address location. For a processor, a load occurs as the result of executing a particular instruction. Whether the load results in the Requester issuing a Read transaction depends on whether the accessed cache line is held in the local cache.

See also [Speculative read](#), [Store](#).

Main memory The memory that holds the data value of an address location when no cached copies of that location exist. For any location, main memory can be out of date with respect to the cached copies of the location, but main memory is updated with the most recent data value when no cached copies exist neither in the RNs nor in the Interconnect.

Main memory can be referred to as memory when the context makes the intended meaning clear.

Requester *See [Requester on page 1-25](#).*

Requester component

A component that initiates transactions.

It is possible that a single component can act as both a Requester component and as a Subordinate component. For example, a Direct Memory Access (DMA) component can be a Requester component when it is initiating transactions to move data, and a Subordinate component when it is being programmed.

See also [Component](#), [Interconnect component](#), [Subordinate component](#).

Memory Management Unit (MMU)

Provides detailed control of the part of a memory system that provides address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

See also [System Memory Management Unit \(SMMU\)](#).

Memory Subordinate component

A Memory Subordinate component, or *Memory Subordinate*, is a Subordinate component with the following properties:

- A read of a byte from a Memory Subordinate returns the last value written to that byte location.
- A write to a byte location in a Memory Subordinate updates the value at that location to a new value that is obtained by subsequent reads.
- Reading a location multiple times has no side-effects on any other byte location.
- Reading or writing one byte location has no side-effects on any other byte location.

See also [Component](#), [Requester component](#), [Peripheral Subordinate component](#).

Message

See [Message on page 1-24](#).

Observer

A processor or other Requester component, such as a peripheral device, that can generate reads from or writes to memory.

Outstanding Request

A transaction is outstanding from the cycle that the Request is first issued until either:

- The transaction is fully completed, as determined by the return of all responses that are expected for the transaction.
- It receives RetryAck and PCrdGrant and is either:
 - Retried using a credit of the appropriate PCrdType, and then is fully completed as determined above.
 - Canceled, and returns the received credit using the PCrdReturn message.

Peer node

A protocol node of the same type with reference to itself. For example, the peer node for a Request Node is another Request Node.

Peer to Peer

Communication between the same type of nodes. For example, from one RN to another RN.

See also [Downstream](#), [Upstream](#).

Peripheral Subordinate component

A Peripheral Subordinate component is also described as a *Peripheral Subordinate*. This specification recommends that a Peripheral Subordinate has an IMPLEMENTATION DEFINED method of access that is typically described in the data sheet for the component. Any access that is not defined as permitted might cause the Peripheral Subordinate to fail, but must complete in a protocol-compliant manner to prevent system deadlock. The protocol does not require continued correct operation of the peripheral.

See also [Memory Subordinate component](#), [Subordinate component](#).

Permission to store

A component has permission to store if it can perform a store to the associated cache line without informing any other components or the interconnect.

Packet

See [Packet on page 1-24](#).

Phit

See [Phit on page 1-24](#).

PoC

See [PoC on page 1-24](#).

PoS

See [PoS on page 1-24](#).

PoP

See [PoP on page 1-24](#).

Prefetching	<p>Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.</p> <p>In this specification, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.</p>
Protocol Credit	See Protocol Credit on page 1-25 .
Requester	See Requester on page 1-25 .
RN	See RN on page 1-25 .
Subordinate	See Subordinate on page 1-25 .
Subordinate component	<p>A component that receives transactions and responds to them.</p> <p>It is possible that a single component can act as both a Subordinate component and as a Requester component. For example, a Direct Memory Access (DMA) component can be a Subordinate component when it is being programmed and a Requester component when it is initiating transactions to move data.</p> <p>See also Requester component, Memory Subordinate component, Peripheral Subordinate component.</p>
SN	See SN on page 1-25 .
Snooped cache	A hardware-coherent cache that receives Snoop transactions.
Snoop filter	A snoop filter is able to track the cache lines that might be allocated within a Requester.
Speculative read	<p>A transaction that a component issues when it might not need the transaction to be performed because it already has a copy of the accessed cache line in its local cache. Typically, a speculative read is performed in parallel with a local cache lookup. This gives lower latency than looking in the local cache first, and then issuing a Read transaction only if the required cache line is not found in the local cache.</p> <p>See also Load.</p>
Stash	The action of placing data in a cache closer to the agent that is expected to be the next user of the data.
Store	<p>The action of a Requester component changing the value held at a particular address location. For a processor, a store occurs as the result of executing a particular instruction. Whether the store results in the Requester issuing a Read or Write transaction depends on whether the accessed cache line is held in the local cache, and if it is in the local cache, the state it is in.</p> <p>See also Load, Permission to store.</p>
Synchronization barrier	See Barrier .
System Memory Management Unit (SMMU)	<p>A system-level MMU. That is, a system component that provides address translation from one address space to another. An SMMU provides one or more of:</p> <ul style="list-style-type: none"> • <i>Virtual Address (VA) to Physical Address (PA)</i> translation. • <i>VA to Intermediate Physical Address (IPA)</i> translation. • <i>IPA to PA</i> translation. <p>See also Memory Management Unit (MMU).</p>
TLB	See Translation Lookaside Buffer (TLB) .
Transaction	See Transaction on page 1-24 .

Translation Lookaside Buffer (TLB)

A memory structure containing the results of translation table walks. TLBs help to reduce the average cost of a memory access.

See also [System Memory Management Unit \(SMMU\)](#), [Translation table](#), [Translation table walk](#).

Translation table

A table held in memory that defines the properties of memory areas of various sizes from 1KB.

See also [Translation Lookaside Buffer \(TLB\)](#), [Translation table walk](#).

Translation table walk

The process of doing a full translation table lookup.

See also [Translation Lookaside Buffer \(TLB\)](#), [Translation table](#).

Unaligned

An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Unaligned memory accesses

Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

See also [Aligned](#).

UNPREDICTABLE

In the AMBA Architecture means that the behavior cannot be relied upon.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

When UNPREDICTABLE appears in body text, it is always in small capitals.

Upstream

A transaction operates between a Requester component and one or more Subordinate components, and can pass through one or more intermediate components. At any intermediate component, for a given transaction, *upstream* means between that component and the originating Requester component, and includes the originating Requester component.

Downstream and upstream are defined relative to the transaction as a whole, not relative to individual data flows within the transaction.

See also [Downstream](#), [Requester component](#), [Peer to Peer](#), [Subordinate component](#).

Write-Back cache

A cache in which, when a store is permitted to store, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to next level cache or main memory when the cache line is cleaned or re-allocated. Another common term for a Write-Back cache is a *Copy-Back* cache.

Write-Invalidate protocol

See [Write-Invalidate protocol on page 1-26](#).
